> What Dr. Dingle has done is to reopen the question of the relation of mathematical physics to experimental physics, since he claims to detect a new and perverted point of view in the former. Now a system of mathematical physics, apart from the alleged perversion, is the working out of the mathematical consequences of certain hypotheses. The worth of the theory is judged…by the closeness of the agreement of its predictions with the results of observation, and also the number of phenomena which it can so predict from the one set of hypotheses. The scientific attitude is, not to cavil at the attempt, but to see if it is successful.

This is an absolutely standard interpretation of how the H-D method works. Throughout his own writings, beginning right from his inaugural lecture in Oxford (Milne 1929), Milne had subscribed to precisely the same interpretation of the Hypothetico-Deductive (H-D) method. Whatever the controversy is about, the issue is not how to interpret hypothetico-deductivism. That much is evident.

Moreover, it is quite clear that Dingle et al. are not mounting opposition to something we, today, would consider philosophically radical; rather, they are objecting to what, today, would be considered completely unobjectionable. Given today's acceptance of the H-D method, yet its rejection by otherwise well-regarded scientists at that time, it seems to follow that it was, at least in part, this debate and its followup which settled the issue. In any case, Dingle and his supporters generally went silent, restricting their activities for the most part to books, or relatively positive statements of their own positions. (A.D.R. 1938, Dingle 1938) Things settled down, just in time for the War.

7. The Calm Between the Storms

During the next several years, it became evident that Milne's methods, and kinematic relativity as well, had reached respectability. One important sign of this progress was exhibited at an early 1939 joint meeting between the Royal Astronomical Society and the Physical Society of London, The meeting had as its goal a thorough review of the situation in cosmology. McVittie was chosen to present the observational situation; his report was soon published. (McVittie, 1939) Reviewing the theoretical situation was George Temple, one of the most highly respected mathematicians of the time. Temple's report saw print almost immediately. (Temple 1939) Within a short time, Temple's paper took on the role of successor to Robertson's definitive 1933 “Relativistic Cosmology.” (Robertson 1933b)

7.1 Two Equal Competitors

Both McVittie and Temple presented kinematic relativity and relativistic cosmology as equal competitors in accounting for the cosmological observations. Unfortunately, as McVittie noted, observations could not, at that time, discriminate between the two theories. Temple's analysis of Milne's work praises its simplicity and elegance, and refers in particular to its operationalism and axiomatization, which “start from a completely novel discussion of the correlation of measurements made by different observers in terms of light signals only.” (Temple 1939, p. 468) Throughout the rest of his discussion of the two theories, Temple utilizes Milne's light-signal correlation method, explicitly rejecting rigid-rod transport for distance measurement. Milne's methods have triumphed.

Later that year McCrea publishes an important paper in *Philosophy of Science*. (McCrea 1939) Put most simply, the paper starts out to defend Milne's methods, but ends up by presenting a full-blown and interesting, although quite unhistorical, account of the evolution and structure of physical theories.

7.2 The Origin and Evolution of Theories

McCrea's overall view is that theories are set up to be hypothetico-deductive in structure. His account is based on his view of the evolution of theories of space-time and mechanics, beginning with Newton, through the General Theory of Relativity and ending in kinematic relativity. His argument reduces to the claim that, insofar as Milne and e.g., Newton, can be shown to follow the same procedure, any attack upon Milne is also an attack upon Newton. First, he states his goals in the paper.

The first goal is to emphasise how each theory leaves us in a position in which the succeeding one appears as a perfectly natural next step in the development of ideas. (McCrea 1939, p. 137) McCrea embeds this argument in an account of how analogue models (à la Campbell) are used to set up new theories—this is essentially an account of how discovery might proceed in linking an older theory with its successor.The second goal is to show how, in spite of superficial differences in character, the theories in question all necessarily possess the same general structure constituted by the presence of hypotheses, from which certain general mathematical relations are deduced, which in their turn are used to predict

relations between observable quantities. As McCrea notes, “this study may claim an interest of its own, but it is presented also for a further reason” namely, that

> it has been contended [by Dingle, most especially] that theories like Milne's represent a fundamentally new outlook on the part of some theorists, in that such theories are purely mental constructs divorced from experince of the physical world. We shall see that on the contrary Milne's theory is easily brought into line with the others in such a way that this criticism is neither more nor less true of it than of the rest. (McCrea 1939, p. 138)

In McCrea's discussion of the theories he asserts that “the consituents [of the theories themselves] which are of physical significance are sets of mathematical relations, coupled with sets of rules of interpretation” which yield, “after observational test, descriptions rather than explanations of physical phenomena.” According to McCrea, one real advantage of his view is that it “leads to simple criteria for comparing the merits of different theories.” Finally, on the metaphysics of the original hypotheses, McCrea claims that “the initial hypotheses from which the mathematical relations are deduced do not ultimately have any direct physical significance.”

McCrea's paper, published in the leading philosophy of science journal of the time, is the final imprimateur on Milne's views.

7.3 Milne's Ultimate Success

Three years later, Milne was awarded the James Scott prize, the most prestigious award for ‘natural philosophy’ in the Anglophone world. Milne's lecture title is telling: “Fundamental Concepts of Natural Philosophy.” (Milne 1943) Although Milne does concede to Dingle that he no longer believes that it is possible to deduce physics completely in the absence of reference to phenomena, for the most part his award lecture is a long reiteration of his previous twelve years' work in cosmology.

One year later, Milne received his ultimate accolade, election as president of the Royal Astronomical Society. In his inaugural lecture, Milne again reviews his work, but adds two remarks of interest. First, he modifies his earlier view that theories are acceptable solely on the basis of their successful predictive power; to this, he now adds that a theory cannot be accepted as satisfactory unless it is philosophically satisfying. (Milne 1943, p. 120) Secondly, on a personal note, he admits that he is still amazed at the outcry that his theory and its philosophy caused. Milne here is being a bit disingenuous. In many places in his letters he not only recognizes the outcry, he delights in it, and seeks to provoke it even more. (Milne 1932-37, 12 May 35; 28 Jul 36)

From this point onward, cosmology's philosophy is no longer directly influenced by Milne himself. Moreover, kinematic relativity began to stagnate as a research programme; except for Whitrow, Milne had no new students, and failed to attract any new converts to the theory. His work was done. But his philosophical influence didn't end, in fact it wasn't to crest until the end of the 40s in the work of another man, Hermann Bondi. Again, however, a storm was generated by Milne's methods, even though they

were now in the hands of another.

8. Steady-state Cosmology

In 1948, a young mathematician, Herman Bondi, in concert with two close friends Thomas Gold and Fred Hoyle, proposed a radical new cosmological theory, the *Steady State* theory. This theory differs from the basic picture shared by both kinematic relativity and relativistic cosmology, namely, that of a universe with a definite origin in a small, dense knot, followed by evolution into the universe we have today. According to Bondi's theory, the universe as far back into the past as we might look would always look the same; there was no evolution, there could be no “fossils”, as Bondi called putative evidence of a universe different in the past from our present one. What we observe today is the same state of a universe that has been and always will be steady. Bondi came to his notion of the steady state primarily from his commitment to the philosophical components of Milne's work, most especially the methodology of rationalism plus hypothetico-deductivism; additionally, Bondi coupled to these Milnean notions some ideas taken directly from the philosophy of Karl Popper.

8.1 Bondi's Philosophical Origins

Bondi reveals his philosophical commitments in several ways. First, he argues against induction and extrapolation from small-scale experiment, that is, against the inductive empiricism of Dingle et al. Secondly, he argues in favor of hypothesis and deduction, that is, in favor of Milne et al. Finally, he specifically remarks the excellence of Milne's Methods, and the theory—kinematic relativity—created therefrom, and remarks the significance of these elements in the creation of his version of the new steady-state cosmology.

From the very beginning Bondi admits the validity of both positions in the methodological debate:

> In particular, there are two important approaches to the subject [cosmology] so different from each other that it is hardly surprising that they lead to different answers...The contrast between the 'extrapolating' and the 'deductive' attitudes to cosmology is very great indeed. (Bondi 1960), p. 3-5)

The *extrapolating* approach, which Bondi sometimes calls the *empirical school*, is represented by Dingle, McVittie, and their colleagues. Opposed to the extrapolative approach is the *deductive* approach, which “is reached from investigations in the borderland between physics and philosophy.” Milne is obviously the major proponent of this view. Although Bondi finds good points in both approaches, he also finds problems in both approaches. In the end, cosmology is the worse for excesses from **either** end of the spectrum:

> Just as some adherents of the ‘empirical’ school tend to regard cosmology as a testing ground for their extrapolations and as a legitimate playground for the geometers, so some

> adherents of the deductive approach appear to regard cosmology as a purely logical subject. (Bondi 1960, p. 7)

In this latter case, the deductive extremists, in their mathematical zeal, seem to forget that cosmology, after all, **should** have some relation to observation: “To them all that is of interest in a theory is its logical character, not its relevance to the interpretation of observational data.” Obviously, this danger must be avoided: according to Bondi, deductivism can be a ***scientific*** approach in cosmology only if its postulates (or axioms) are candidates for disproof.

8.2 Enter Popper

Clearly, with this reference to the connection between science and disproof, Bondi has added a distinctly Poppererian element to the deductivist methodology, one which had not previously appeared in the works of any of the earlier members of the hypothetico-deductive school. According to Popper's philosophy of science, a theory can legitimately be called “scientific” only if that theory makes a prediction that, in principle, can be shown to be false, or *falsified*, to use Popper's own term. Thus astrology, for example, fails to be a scientific theory because it cannot be falsified: although astrology seems to make predictions, these statements about the future are so vague, so general and abstract, that they cannot be tied down to definite claims about observations to be made at a definite time and place. Hence there is no explicit observation to be made in falsification. Astronomy, in comparison, makes explicit, specific predictions about what will occur in the sky on such-and-such a date, in such-and-such a place. If the prediction fails, then we know that the element of astronomical theory which made the prediction is deficient, maybe even false.

Cosmology is a borderline case: since observations of cosmological significance are so rare and hard-won—Hubble's observation of the red shift was one of the first solid ones—it is very difficult, not to mention brave, to tie one's cosmological theory to Popper's falsificationist principle as a guarantee of scientific acceptability. But this is exactly what Bondi did.

Much later Bondi was to make explicit his debt to Popper:

> I think the person from whom we had most help on the philosophical side was Popper. His analysis of science encouraged one to be imaginative, and encouraged one to go for something that was very rigid and therefore empirically disprovable. (Bondi 1990, p. 194)

8.3 But It's Milne In the End

Yet Bondi's major philosophical debt was to Milne. According to Bondi, Milne's theory was through and through deductive, which was reason enough for some of his colleagues to condemn it:

> The aim of this discipline [= kinematic relativity] is to deduce as much as possible merely from the cosmological principle and the basic properties of space, time and the propagation

> of light. The beauty of this, as indeed of any deductive theory, rests on the rigour of the arguments and the small number of the axioms required...When the theory was first developed it met with great hostility and was criticized very severely, often unjustly, and sometimes frivolously. (Bondi 1960), p. 123)

In addition to his admiration of Milne's H-D methodology, Bondi has high praise as well for Milne's operationalism, particularly its use in defining distance:

> Imperfect as Milne's definition of distance may be, it is very much better than the ‘rigid ruler’ one used in most other theories…Milne's definition of distance, by no means perfect as it is, is probably the best yet devised. (Bondi 1960, p. 126-9)

In the end, Bondi sums up Milne's contributions with no uncertain praise:

> The foregoing brief description will have indicated the remarkable success of kinematic relativity in attempting to use the cosmological principle not only for the construction of the substratum but as chief guide in formulating ordinary physics. In this respect it differs greatly from all other cosmologies which either rely on a conventionally obtained body of physics or have not yet succeeded in drawing conclusions of local interest from the cosmological principle. (Bondi 1960, p. 136)

8.4 Return of the Cosmological Principle

Here Bondi speaks of Milne's cosmological principle. According to Milne's principle, every observer in the universe should get the same world picture, that is, should make precisely the same observations of the universe at the same moment as any other observer. (Milne 1934b) Uniformity over spatial slices is guaranted by Milne's invoking of the principle. Yet Milne's universe evolves, it changes its form over time. Hence it has no temporal uniformity. Bondi felt that this raised the possibility that physics itself might change over time. Because of this risk, Bondi generalized Milne's cosmological principle into what he called the *perfect cosmological principle* [=PCP]. According to this principle, all observers at all places and **at all times** will look out upon the same unchanging, unevolving, universe. Such a universe is a universe in a steady-state—hence the name.

Clearly, PCP is a daring, indeed heroic, interpretation of a methodological necessity. Forty years after the fact, Bondi described the “philosophical attitude” which underlay his “implausible” PCP:

> But the essential point of the philosophy was and is that if the universe was evolving and changing, then there is no reason to trust what we call the laws of physics, established by experiments performed here and now, to have permanent validity. (Bondi 1990, p. 192)

Hence, or so Bondi's argument goes, since there is reason **not** to trust the laws of physics if the universe is evolving, let us presume that the universe is **not** evolving and changing; that is, let us presume PCP.

Although the principle (and the theory which results from it—steady state cosmology) is, as McVittie remarked, "much more restrictive than general relativity"; (McVittie 1990, p. 45) it is this very restrictiveness which satisfies Bondi's Popperian wishes:

> For the correct argument has always been that the steady state model was the one that could be disproved most easily by observation, Therefore, it should take precedence over other less disprovable ones until it has been disproved. (Bondi and Kilmister 1959, p. 55-6)

In another place, Bondi makes a similar point: "Comparison with observation becomes then possible and renders the PCP liable to observational disproof. This possibility of a clear-cut disproof establishes the scientific status of PCP." (Bondi 1957, p. 198) Comments such as this make clear Bondi's committment to a Popperian addition to the basic deductive methodology he inherited from Milne.

8.5 A Popperian Conclusion

In the end, the philosophical purity of Bondi's steady state theory served him, and cosmology, well. Of course, the usual suspect, Dingle, and others of his ilk, such as McVittie in particular, were outraged, and loudly, at Bondi's extension of Milne's methods. A passage from Dingle's R.A.S. Presidential Address suffices to show the tenor of the debate's declining days:

> Even idle speculation may not be quite valueless if it is recognized for what it is. If the new cosmologists would observe this proviso, calling a spade a spade and not a perfect agricultural principle, one's only cause for regret would be that such great talents were spent for so little profit. (Dingle 1953, p. 404)

But PCP and the theory which it engendered were exactly as described: eminently falsifiable. No matter the extent of Dingle *et al*'s disdain, Steady State theory stayed right out in front, ready for whatever empirical observations might be slung at it. As Bondi said "Show me some fossils from an evolving universe, and I'll give it up." In 1965, the fossils arrived, courtesy of the observations of the 3° K remnant microwave radiation.

And Bondi, true to his philosophy, gave it up.

Early Philosophical Interpretations of General Relativity

Each of the following philosophical interpretations of general relativity selected certain aspects of that theory for favored recognition. While followers of Mach lauded Einstein's attempt to implement a "relativization of inertia" in the general theory, they were much more comfortable with Einstein's operationalist treatment of concepts in the special theory. Kantians and neo-Kantians, if freed from strict fealty to the doctrine of the Transcendental Aesthetic, pointed to the surpassing importance of certain synthetic "intellectual forms" in the general theory, such as the principle of general covariance. For logical empiricism, the philosophical significance of relativity theory was largely methodological, that conventions must first be laid down in order to express the empirical content of a physical theory. Finally, within a few years of its completion in 1915, attempts were made to extend general relativity's "geometrization" of gravitation to non-gravitational fields. The first of these, by Weyl, and shortly thereafter by Eddington, may be distinguished from others, in particular the many attempts of Einstein, in that they aimed not at a unified field theory, in the sense of a completely geometrical field theory of all fundamental interactions, but at reconstructing general relativity from the epistemological perspectives of transcendental idealism.

1. The Search for Philosophical Novelty

Extraordinary public clamor greeted an announcement of the joint meeting of the Royal Society of London and the Royal Astronomical Society on the 6th of November, 1919. To within acceptable margin of error, astronomical observations during the solar eclipse the previous May 29th revealed the displacement of starlight passing near the surface of the sun predicted by Einstein's gravitational theory

of curved spacetime. By dint of having "overthrown" such a permanent fixture of the cognitive landscape as Newtonian gravitational theory, the general theory of relativity at once became a principal focus of philosophical interest and inquiry. Although some physicists and philosophers initially opposed it, mostly on non-physical grounds, surveyed here are the principal philosophical interpretations of the theory accepting it as a definite advance in physical knowledge. Even so, these include positions ill-informed as to the mathematics and physics of the theory. Further lack of clarity stemmed from the scientific *literati* who provided differing, and at times, conflicting mathematical or physical accounts of the theory's fundamental principles. These are: the principles of equivalence, of general relativity, of general covariance, and finally what Einstein termed "Mach's Principle" of the complete relativization of inertia. In one or another form, all of these controversies have continued into the present literature of physics and philosophy of physics. (See e.g., Ohanian (1977); Norton (1993); Friedman (1983); Barbour and Pfister (1995).) This is not unusual: physical theories, if sufficiently robust, are rarely, if ever, without unproblematic aspects, often taken to say different things at different stages of development. But the very fluidity of physical and mathematical meaning lent interpretative latitude for inherently antagonistic philosophical viewpoints seeking vindication, confirmation or illumination by the revolutionary new theory. Perhaps only semi-facetiously, Russell (1926, 331) observed that

> There has been a tendency, not uncommon in the case of a new scientific theory, for every philosopher to interpret the work of Einstein in accordance with his own metaphysical system, and to suggest that the outcome is a great accession of strength to the views which the philosopher in question previously held. This cannot be true in all cases; and it may be hoped that it is true in none. It would be disappointing if so fundamental a change as Einstein has introduced involved no philosophical novelty.

It cannot be denied that general relativity proved a considerable stimulus to "philosophical novelty". But then the question as to whether it particularly supported any one line of philosophical interpretation over another also must take into account the fact that schools of interpretation in turn "evolved" to accommodate what were regarded as its philosophically salient features. A classic instance of this is the assertion, to become a cornerstone of logical empiricism, that relativity theory had shown the untenability of any "philosophy of the synthetic *a priori"*, despite the fact that early works on relativity theory by both Reichenbach and Carnap were written from within that broad perspective. It will be seen that, however ideologically useful, this claim by no means "follows" from relativity theory although, as physicist Max von Laue noted in his early text on general relativity (1921, 42), "not every sentence of *The Critique of Pure Reason"* might still be held intact. What does "follow" from scrutiny of the various philosophical appropriations of general relativity is rather a consummate illustration that, due to the evolution and mutual interplay of physical, mathematical and philosophical understandings of a revolutionary physical theory, significant "philosophical interpretations" often are works in progress, extending over many years.

2. Machian Positivism

2.1 In the Early Einstein

In 1912, Einstein's name, together with those of the Göttingen mathematicians David Hilbert and Felix Klein, was prominently displayed (in the *Naturwissenschaftliche Rundschau* 27, 336) among those joining Mach's in a call for the formation of a "Society for Positivist Philosophy". Citing the pressing need of science "but also of our age in general" for a "comprehensive world view based on the material facts accumulated in the individual sciences", the appeal appears above all to have been an orchestrated attempt to buttress Mach's positivist conception of science in the face of recent realist criticisms of Mach by Max Planck, then Germany's leading theoretical physicist. More a declaration of allegiance than an act of scholarly neutrality, it provides but further evidence of Einstein's youthful enthusiasm for Mach's writings. Late in life (1949a, 21), Einstein wrote of the "profound influence" that Mach's *Science of Mechanics* (1883) exercised upon him as a student as well as of the "very great influence" in his "younger years" of "Mach's epistemological position". Indeed, in first decade or so of relativity theory, these influences are highly visible. Already in the special theory of relativity (1905), Einstein's operational definition of the "simultaneity" of distantly separated events, whereby clocks are synchronized by sending and receiving light signals, is closely modeled on the operational definition of "mass" in Mach's *Mechanics.* Moreover, occasional epistemological and methodological pronouncements indicated a broad consensus with core parts of Mach's epistemology of science, e.g., "The concept does not exist for the physicist until he has the possibility of discovering whether or not it is fulfilled in an actual case" (1917a/1955, 22). Thus relativity theory was widely viewed as fully compliant with Mach's characterization of theoretical concepts as merely economical shorthand for concrete observations or operations.

2.2 A "Relativization of Inertia"?

Machian influences specific to the general theory of relativity appeared even more extensive. In papers leading up to the definitive presentation of the general theory of relativity in 1916, Einstein made no secret of the fact that Mach had been the inspiration for his epistemologically mandated generalization of the principle of relativity. Holding, with Mach, that no observable facts could be associated with the notions of "absolute acceleration" or "absolute inertia" (i.e., resistance to acceleration), the generalization mandated that the laws of nature be completely independent of the state of motion of any chosen reference system. On Mach's death, Einstein wrote, in a warm obituary, of how close Mach himself had been, years before, to demanding a general theory of relativity, quoting extensively from the famous passages in the latter parts of the *Mechanics* critical of Newton's "absolute" concepts of space, time and motion (1916b, 102-3). With this reference in mind, the physicist Phillip Frank, later to be associated with the Vienna Circle, observed (1917/1949, 68) that "it is universally known today that Einstein's general theory of relativity grew immediately out of the positivistic doctrine of space and motion". In fact, there are both genuine and spurious Machian motivations connected with Einstein's principle of general relativity, a mixture complicated by Einstein's own puzzling remarks regarding the principle of general covariance.

2.3 Positivism and the "Hole Argument"

A passage from §3 of Einstein's first complete exposition of the general theory of relativity (1916a)

appeared to provide further grist for the mill of Machian positivism. There Einstein grandly declared that his requirement of general covariance for the gravitational field equations (i.e., that they remain unchanged under arbitrary, but suitably continuous, transformation of the spacetime coordinates), "takes away from space and time the last remnant of physical objectivity". An accompanying heuristic "reflection" on the reasoning behind this claim seemed nothing less than an endorsement of Mach's phenomenalism. "All our space-time verifications", Einstein wrote, "invariably amount to a determination of space-time coincidences....". This is because, Einstein presumed, all results of physical measurement ultimately amount to verifications of such coincidences, such as the observation of the coincidence of the second hand of a clock with a mark on its dial. Observing that such (topological) relations alone are preserved under arbitrary coordinate transformation, Einstein concluded that "all our physical experience can ultimately be reduced to such coincidences". To Mach's followers, Einstein's illustrative reflection was nothing less than an explicit avowal of the centerpiece of Mach's phenomenalist epistemology, that sensations *(Empfindungen)*, directly experienced sensory perceptions, alone are real and knowable. Thus Josef Petzoldt, a Machian philosopher and editor of the 8th edition of Mach's *Mechanics* , the first to appear after the general theory of relativity, noted that Einstein's remarks meant that the theory "rests, in the end, on the perception of the coincidence of sensations" and so "is fully in accord with Mach's world-view, which is best characterized as relativistic positivism" (1921, 516).

However, contemporary scholarship has shown that Einstein's remarks here were but elliptical references to an argument (the so-called "Hole Argument") that has only fully been reconstructed from his private correspondence. Its conclusion is that, if a theory is generally covariant, the points of the spacetime manifold can have no inherent primitive individuality (inherited say, from the underlying topology), and so no reality independent of physical fields (Stachel (1980); Norton (1984), (1993)). Thus for a generally covariant theory, no physical reality accrues to "empty space" (or "spacetime") in the absence of physical fields. This means that the spacetime coordinates are nothing more than arbitrary labels for the identification of physical events, or, with rhetorical embellishment, that space and time have lost "the last remnant of physical objectivity". Hence this passage was not an endorsement of positivist phenomenalism.

2.4 "Mach's Principle"

To be sure, for a number of years Einstein expressed the ambition of the general theory of relativity to fully implement Mach's program for the relativization of all inertial effects, even appending the so-called "cosmological constant" to his field equations (1917b) for this purpose. This real point of contact of Mach's influence was clearly identified only in 1918, when Einstein distinguished what he baptized as "Mach's Principle" (roughly, that inertial effects stem from an interaction of bodies) from the principle of general relativity which he now interpreted as the principle of general covariance. Taken together with the principle of the equivalence, Einstein asserted that the three principles, were three "points of view" on which his theory rested, even if they could not be thought completely independent of one another. Despite Einstein's intent, there is considerable disagreement about the extent to which, if at all, general relativity conforms to "Mach's Principle". In part this is due to vagaries regarding what the Principle actually asserts and then again, to difficulties in comprehending what physical mechanism might implement the Principle, however interpreted. How, for instance, could a body's inertial mass be accounted due to the

influence of all other bodies in the universe? (See the discussions in Barbour and Pfister (1995)).

2.5 An Emerging Anti-Positivism

As Einstein's principal research activity turned, after 1919, to the pursuit of a geometrical "unified theory of fields", his philosophical pronouncements increasingly took on a realist or at least anti-positivist coloration. Already in (1922, 28) lecturing at the Sorbonne, Einstein pronounced Mach "*un bon mécanicien*" (no doubt in reference to Mach's views of the relativity of inertia) but "*un déplorable philosophe*". Increasingly, Einstein's retrospective portrayals of the genesis of general relativity centered almost entirely on considerations of mathematical aesthetics (see Norton (2000) and §5). On the other hand, positivists and operationalists alike adopted the Einstein analysis of simultaneity as relativity theory's fundamental methodological feature. One, ruefully noting the difficulty of giving an operationalist analysis of the general theory, even suggested that the requirement of general covariance "conceals the possibility of disaster" (Bridgman (1949), 354). Finally there was, for Einstein, an understandable awkwardness in learning of Mach's surprising disavowal of any role as forerunner to relativity theory in the "Preface", dated 1913, to his posthumous book (1921) on physical optics, published by Mach's son Ludwig. Though Einstein died without knowing differently, a recent investigation has built a strong case that this statement was forged after Mach's death by his son Ludwig, under the influence of a rival guardian of Mach's legacy and opponent of relativity theory, the philosopher Hugo Dingler (Wolters, 1987).

3. Kantian and Neo-Kantian Interpretations

3.1 Neo-Kantians on Special Relativity

In the universities of Imperial and early Weimar Germany, the philosophy of Kant, particularly the various neo-Kantian schools, held pride of place. Of these, the "Marburg School" of Hermann Cohen and Paul Natorp, later Ernst Cassirer, exhibited a special interest in the philosophy of the physical sciences and of mathematics. But prior to the general theory of relativity (1915-1916), Kantian philosophers accorded relativity theory only cursory attention. This may be seen in two leading Marburg works appearing in 1910, Cassirer's *Substanzbegriff und Funktionsbegriff*. and Natorp's *Die Logischen Grundlagen der Exakten Wissenschaften*. Both conform to the characteristic Marburg modification of Kant that greatly extended the scope of "transcendental logic", bringing under "pure thought" or "intellectual forms" what Kant had sharply distinguished as "pure intuition" and a conceptual faculty of understanding. Of course, this revisionist tendency greatly transformed the meaning of Kant's Transcendental Aesthetic and with it Kant's conviction that space and time were "forms of sensibility" or "pure intuitions *a priori"* and so as well, his accounts of arithmetic and geometry. As will be seen, it enabled Cassirer, some ten years later, to view even the general theory of relativity as a striking confirmation of the fundamental tenets of transcendental idealism. In 1910, however, Cassirer's brief but diffuse discussion of "the problem of relativity" mentions neither the principle of relativity nor the light postulate nor the names of Einstein, Lorentz or Minkowski. Rather it centers on the question of whether

space and time are aggregates of sense impressions or "independent intellectual *(gedankliche)* forms". Having decided in favor of the latter, Cassirer goes on to argue how and why these ideal mathematical presuppositions are necessarily related to measurable, empirical notions of space, time, and motion (1910, 228-9; 1923, 172-3).

Natorp's treatment, though scarcely six pages is far more detailed (1910, 399-404). In Marburg revisionist fashion, the "Minkowski *(sic)* principle of relativity" was welcomed as a more consistent (as avoiding "Newtonian absolutism") carrying through of the distinction between transcendentally ideal and purely mathematical *concepts* of space and time and the relative physical measures of space and time. The relativization of time measurements, in particular, showed that Kant, shorn of the psychologistic error of "pure intuition", had correctly maintained that time is not an object of perception. Natorp further alleged that from this relativization it followed that events are ordered, not in relation to an absolute time, but as lawfully determined phenomena in mutual temporal relation to one another. This is close to a Leibnizian relationism about time. Similarly, the light postulate had a two-fold significance within the Marburg conception of natural science. On the one hand, the uniformity of the velocity of light, deemed an *empirical* presupposition of all space- and time-measurements, reminded that absolute determinations of these measures, unattainable in empirical natural science, would require a correspondingly absolute bound. Then again, as an upper limiting velocity for physical processes, including gravitational force, the light postulate eliminated the "mysterious absolutism" of Newtonian action-at-a-distance. Natorp regarded the requirement of invariance of laws of nature with respect to the Lorentz transformations as "perhaps the most important result of Minkowski's investigation". However, little is said about this, and in fact there is some confusion regarding these transformations and the Galilean ones they supercede (the former are seen as a "broadening *(Erweiterung)* of the old supposition of the invariance of Newtonian mechanics for a translatory or *circular* (*zirkuläre*, emphasis added) motion of the world coordinates"(403)). He concluded with an observation that the appearance of non-Euclidean and multi-dimensional geometries in physics and mathematics are to be understood only as "valuable tools in the treatment of special problems". In themselves, they furnish no new insight into the (transcendental) logical meaning and ground of the purely mathematically determined concepts of space and time; still less do they require the abandonment of these concepts.

3.2 Immunizing Strategies

Following the experimental confirmation of the general theory in 1919, few Kantians attempted to retain, unadulterated, all of the components of Kant's epistemological views. Several examples will suffice to indicate characteristic "immunizing" strategies (see Hentschel (1990). The *Habilitationsschrift* of E. Sellien (1919), read by Einstein in view of his criticism expressed in an October, 1919 letter to Moritz Schlick (Howard (1984),625), declared that Kant's views on space and time pertained solely to "intuitive space" and so were not touched by the measurable spaces and times of Einstein's empirical theory. The work of another young Kantian philosopher, Ilse Schneider, personally known to Einstein, affirmed that Kant merely had held that the space of three-dimensional Euclidean geometry is the space in which Newton's gravitational law is valid, whereas an analogous situation obtains in general relativity. Furthermore, Einstein's cosmology (1917b) of a finite but unbounded universe could be seen as in complete accord with the "transcendental solution" to the First Antinomy in the Second Book of the

Transcendental Dialectic. Her verdict was that the apparent contradictions between relativity theory and Kantian philosophy disappear on closer examination of both doctrines (1921, 71-75).

3.3 Rejecting or Refurbishing the Transcendental Aesthetic

But most Kantian philosophers did not attempt to immunize Kant from an apparent empirical refutation by the general theory. Rather, their concern was to establish how far-reaching the necessary modifications of Kant must be and whether, on implementation, anything distinctively Kantian remained. Certainly, most at risk appeared to be the claim, in the Transcendental Aesthetic, that all objects of "outer" intuition, and so all physical objects, conform to the space of Euclidean geometry. Since the general theory of relativity employed non-Euclidean (Riemannian) geometry for the characterization of physical phenomena, the conclusion seemed inevitable that any assertion of the necessarily Euclidean character of physical space in finite, if not "infinitesimal", regions, is simply false.

Winternitz (1924) is an example of this tendency that may be singled out on the grounds that it was deemed significant enough to be the subject of a rare book review by Einstein (1924) . Winternitz argued that the Transcendental Aesthetic is inextricably connected to the claim of the necessarily Euclidean character of physical space and so stood in direct conflict with Einstein's theory. It must accordingly be totally jettisoned as a confusing and unnecessary appendage of the fundamental transcendental project of establishing the *a priori* logical presuppositions of physical knowledge. Indeed, these presuppositions have been confirmed by the general theory: They are spatiality and temporality as "unintuitive schema of order" in general (as distinct from any particular chronometrical relations), the law of causality and presupposition of continuity, the principle of sufficient reason, and the conservation laws. Remarkably, the *necessity* of each of these principles was, rightly or wrongly, soon to be challenged by the new quantum mechanics. (For a challenge to the law of conservation of energy, see Bohr, Kramers, and Slater (1924)). According to Winternitz, the *ne plus ultra* of transcendental idealism lay in the claim that the world "is not given but posed *(nicht gegeben, sondern aufgegeben)* (as a problem)" out of the given material of sensation. Interestingly, Einstein, late in life, returns to this formulation as comprising the fundamental Kantian insight into the character of physical knowledge (1949b, 680).

However, a number of neo-Kantian positions, of which that of Marburg was only the best known, did not take the core doctrine of the Transcendental Aesthetic, that space and time are *a priori* intuitions, *à la lettre*. Rather, resources broadly within it were sought for preserving an updated "critical idealism". In this regard, Bollert (1921) merits mention for its technically adroit presentation of both the special and the general theory. Bollert argued that relativity theory had "clarified" the Kantian position in the Transcendental Aesthetic by demonstrating that not space and time, but spatiality (determinateness in positional ordering) and temporality (in order of succession) are *a priori* conditions of physical knowledge. In so doing, general relativity theory with its variably curved spacetime, brought a further advance in the steps or levels of "objectivation" lying at the basis of physics. In this process, corresponding with the growth of physical knowledge since Galileo, each higher level is obtained from the previous through elimination of subjective elements from the concept of physical object. This ever-augmented and revised advance of conditions of objectivity is alone central to critical idealism. For this reason, it is "an error" to believe that "a contradiction exists between Kantian *a priorism* and relativity

theory" (1921,64). As will be seen, these conclusions are quite close to those of the much more widely known monograph of Cassirer (1921). It is worth noting that Bollert's interpretation of critical idealism was cited favorably by Gödel (1946/9-B2, 240, n.24) much later during the course of research which led to his famous discovery of rotating universe solutions to Einstein's gravitational field equations (1949). This investigation had been prompted by Gödel's curiosity concerning the similar denials, in relativity theory and in Kant, of an absolute time.

3.4 General Covariance: A Synthetic Principle of "Unity of Determination"

The most influential of all neo-Kantian interpretations of general relativity was Ernst Cassirer's *Zur Einsteinschen Relativitätstheorie* (1921). Cassirer regarded the theory as a crucial test for *Erkenntniskritik*, the preferred term for the epistemology of Marburg's transcendental idealism. The question, posed right at the beginning, is whether the Transcendental Aesthetic offered a foundation "broad enough and strong enough" to bear the general theory of relativity. Recognizing the theory's principal epistemological significance to lie in the requirement of general covariance ("that the general laws of nature are not changed in form by arbitrary changes of the space-time variables"), Cassirer directed his attention to Einstein's remarks, cited in §2 above, that general covariance "takes away from space and time the last remnant of physical objectivity". Cassirer correctly construed the gist of this passage to mean that in the general theory of relativity, space and time coordinates have no further importance than to be mere labels of events ("coincidences"), independent variables of the mathematical (field) functions characterizing physical state magnitudes. Furthermore,in accord with central tenets of the Marburg Kant interpretation noted above, Cassirer maintained that the requirement of generally covariant laws was a vindication of the transcendental ideality of space and time, not, indeed, as "forms of intuition" but as "objectifying conditions" that further "de-anthropomorphized" the concept of object in physics, rendering it "purely symbolic". In this regard, the requirement of general covariance had significantly improved upon Kant in bringing out far more clearly the exclusively methodological role of these conditions in empirical cognition, a role Kant misleadingly assigned to "pure intuition". Not only has it has shown that space and time are not "things", it has also clarified that they are "ideal principles of order" applying to the objects of the physical world as a necessary condition of their possible experience. According to Cassirer, Kant's *intention* with regard to "pure intuition" was simply to express the methodological presupposition that certain "intellectual forms" *(Denkformen),* among which are the purely ideal *concepts* of coexistence and succession, enter into all physical knowledge. According to the development of physics since the 17th century chronicled in *Substanzbegriff und Functionsbegrif*, these forms have progressively lost their "fortuitous" *(zufälligen)* anthropomorphic features, and more and more take on the character of "systematic forms of unity". From this vantage point, general covariance is but the most recent refinement of the methodological principle of "unity of determination" governing the constitution of objects of physical knowledge, completing the transposition in physics from concepts of substance into functional and relational concepts. In its wake, the fundamental concept of object in physics no longer pertains to particular entities or processes in space and time but rather to "the invariance of relations among (physical state) magnitudes". For this reason, Cassirer concluded, the general theory of relativity exhibits "the most determinate application and carrying through within

empirical science of the standpoint of critical idealism" (1921/1957, 71; 1923, 412).

4. Logical Empiricism

4.1 Lessons of Methodology?

Logical empiricism's philosophy of science was conceived under the guiding star of Einstein's two theories of relativity, as may be seen from the early writings of its founders, for purposes here, Moritz Schlick, Rudolf Carnap, and Hans Reichenbach. The small monograph of Schlick, *Space and Time in Contemporary Physics*, appearing in 1917, initially in successive issues of the scientific weekly *Die Naturwissenschaften*, served as a prototype. Among the first of a host of "philosophical examinations" of the general theory of relativity, it was distinguished both by the comprehensibility of its largely non-technical physical exposition and by Einstein's enthusiastic praise of its philosophical appraisal, favoring Poincaré's conventionalism over both neo-Kantianism and Machian positivism. The transformation of the concept of space by the general theory of relativity was the subject of Rudolf Carnap's dissertation at Jena in 1921. Appearing as a monograph in 1922, it also evinced a broadly conventionalist methodology combined with elements of Husserlian transcendental phenomenology. Distinguishing clearly between intuitive, physical and purely formal conceptions of space, Carnap argues that, subject to the necessary constraints of certain *a priori* phenomenological conditions of the topology of intuitive space, the purely formal and the physical aspects of theories of space, can be adjusted to one another so as to preserve any conventionally chosen aspect. In turn, Hans Reichenbach was one of five intrepid attendees of Einstein's first seminar on general relativity given at Berlin University in the tumultuous winter of 1918-1919; his detailed notebooks survive. The general theory of relativity was the particular subject of Reichenbach's neo-Kantian first book (1920), which is dedicated to Albert Einstein, as well as of his next two books (1924), (1928), and of numerous papers in the 1920s.

But Einstein's theories of relativity provided far more than the subject matter for these philosophical examinations; rather logical empiricist philosophy of science was itself fashioned by lessons allegedly drawn from relativity theory in correcting or rebutting neo-Kantian and Machian perspectives on general methodological and epistemological questions of science. Several of the most characteristic doctrines of logical empiricist philosophy of science — the interpretation of *a priori* elements in physical theories as conventions, the treatment of the role of conventions in linking theory to observation and in theory choice, the insistence on verificationist definitions of theoretical terms — were taken to have been conclusively demonstrated by Einstein in fashioning his two theories of relativity. In particular, Einstein's 1905 analysis of the conventionality of simultaneity in the special theory of relativity became something of a methodological paradigm, prompting Reichenbach's own method of "logical analysis" of physical theories into "subjective" (definitional, conventional) and "objective" (empirical) components. The overriding concern in the logical empiricist treatment of relativity theory was to draw broad lessons from relativity theory for scientific methodology and philosophy of science generally, although issues more specific to the philosophy of physics were also addressed. Only the former are considered here; for a discussion of the latter, we may refer to Ryckman (forthcoming b).

4.2 From the "Relativized A priori to the "Relativity of Geometry"

A cornerstone of Reichenbach's "logical analysis" of the theory of general relativity is the thesis of "the relativity of geometry", that an arbitrary geometry may be ascribed to spacetime (holding constant the underlying topology) if the laws of physics are correspondingly modified through the introduction of "universal forces". This particular argument for metric conventionalism has generated substantial controversy on its own, but is better understood through an account of its genesis in Reichenbach's early neo-Kantianism. Independently of that genesis, the thesis becomes the paradigmatic illustration of Reichenabch's broad methodological claim that conventional or definitional elements, in the form of "coordinative definitions" associating mathematical concepts with "elements of physical reality", are a necessary condition of empirical cognition in science. At the same time, however, Reichenbach's thesis of metrical conventionalism is part and parcel of an audacious program of epistemological reductionism regarding spacetime structures. This was first attempted in his "constructive axiomatization" (1924) of the theory of relativity on the basis of "elementary matters of fact"*(Elementartatbestande)* regarding the observable behavior of lights rays, and rods and clocks. Here, and in the more widely read treatment(1928), metrical properties of spacetime are deemed less fundamental than topological ones, while the latter are derived from the concept of time order. But time order in turn is reduced to that of causal order and so the whole edifice of structures of spacetime is considered epistemologically derivative, resting upon ultimately basic empirical facts about causal order and a prohibition against action-at-a-distance. The end point of Reichenbach's epistemological analysis of the foundations of spacetime theory is then "the causal theory of time", a type of relational theory of time that assumes the validity of the causal principle of action-by-contact *(Nahwirkungsprinzip).*

However, Reichenbach's first monograph on relativity (1920) was written from within a neo-Kantian perspective. As Friedman (1999) and others have discussed in detail (Ryckman, forthcoming a), Reichenbach's innovation, a modification of the Kantian conception of *synthetic a priori* principles, rejecting the sense of "valid for all time" while retaining that of "constitutive of the object (of knowledge)", led to the conception of a theory-specific "relativised *a priori*". According to Reichenbach, any physical theory presupposes the validity of systems of certain, usually quite general, principles, which may vary from theory to theory. Such "coordinating principles", as they are then termed, are indispensable for the ordering of perceptual data; they define "the objects of knowledge" within the theory. The epistemological significance of relativity theory, according to the young Reichenbach, is to have shown, contrary to Kant, that these systems may contain mutually inconsistent principles, and so require emendation to remove contradictions. Thus a "relativization" of the Kantian conception of *synthetic a priori* principles is the direct epistemological result of the theory of relativity. But this finding is also taken to signal a transformation in the method of epistemological investigation of science. In place of Kant's "analysis of Reason", "the method of analysis of science"*(der wissenschaftsanalytische Methode)* is proposed as "the only way that affords us an understanding of the contribution of our reason to knowledge" (1920, 71; 1965, 74). The method's *raison d'être* is to sharply distinguish between the "subjective" role of (coordinating) principles — "the contribution of Reason" — and the "contribution of objective reality", represented by theory-specific empirical laws and regularities ("axioms of connection") which in some sense have been "constituted" by the former. Relativity theory itself is a shining exemplar of this method for it has shown that the metric of spacetime describes an "objective property" of the

world, once the subjective freedom to make coordinate transformations (the coordinating principle of general covariance) is recognized (1920, 86-7; 1965, 90). The thesis of metric conventionalism had yet to appear.

But soon it did. Still in 1920, Schlick objected, both publicly and in private correspondence with Reichenbach, that "principles of coordination" were precisely statements of the kind that Poincaré had termed "conventions" (see Coffa, 1991, 201ff.). Moreover, Einstein, in lecture of January, 1921, entitled "Geometry and Experience", appeared to lend support to this view. Einstein argued that the question concerning the nature of spacetime geometry becomes an empirical question only on certain *pro tem* stipulations regarding the "practically rigid body" of measurement (*pro tem* in view of the inadmissibility in relativity theory of the concept "actually rigid body"). In any case, by 1922, the essential pieces of Reichenbach's "mature" conventionalist view had emerged. The argument is canonically presented in §8 (entitled "The Relativity of Geometry") of *Der Philosophie der Raum-Zeit-Lehre* (completed in 1926, published in 1928). In a move superficially similar to the argument of Einstein's "Geometry and Experience", Reichenbach maintained that questions concerning the empirical determination of the metric of spacetime must first confront the fact that only the whole theoretical edifice comprising geometry and physics admits of observational test. Einstein's gravitational theory is such a totality. However, unlike Einstein, Reichenbach's "method of analysis of science", later re-named "logical analysis of science", is directed to the epistemological problem of factoring this totality into its conventional or definitional and its empirical components.

This is done as follows. The empirical determination of the spacetime metric by measurement requires choice of some "metrical indicators": this can only be done by laying down a "coordinative definition" stipulating, e.g., that the metrical notion of a "length" is coordinated to some physical object or process. A standard choice coordinates "lengths" with "infinitesimal measuring rods" supposed rigid (e.g., Einstein's "practically rigid body"). This however is only a convention, and other physical objects or processes might be chosen. (In Schlick's fanciful example, the Dali Lama's heartbeat could be chosen as the physical process establishing units of time.) Of course, the chosen metrical indicators must be corrected for certain distorting effects (temperature, magnetism, etc.) due to the presence of physical forces. Such forces are termed "differential forces" to indicate that they affect various materials differently. However, Reichenbach argued, the choice of a rigid rod as standard of length is tantamount to the claim that there are no non-differential — "universal" — distorting forces that affect all bodies in the same way and cannot be screened off. In the absence of "universal forces" the coordinative definition regarding rigid rods can be implemented and the nature of the spacetime metric empirically determined, for example, finding that paths of light rays through solar gravitational field are not Euclidean straight lines. Thus, the theory of general relativity, on adoption of the coordinative definition of rigid rods ("universal forces = 0"), affirms that the geometry of spacetime in this region is of a non-euclidean kind. The point, however, is that this conclusion rests on the convention governing measuring rods. One could, alternately, maintain that the geometry of spacetime was Euclidean by adopting a different coordinative definition, for example, holding that measuring rods expanded or contracted depending on their position in spacetime, a choice tantamount to the supposition of "universal forces". Then, consistent with all empirical phenomena, it could be maintained that Euclidean geometry was compatible with Einstein's theory if only one allowed the existence of such forces. Thus whether general relativity affirms a Euclidean or a

non-euclidean metric in the solar gravitational field rests upon a conventional choice regarding the existence of "universal forces". Either hypothesis may be adopted since they are empirically equivalent descriptions; their joint possibility is referred to as "the relativity of geometry". Just as with the choice of "standard synchrony" in Reichenbach's analysis of the conventionality of simultaneity, also held to be "logically arbitrary", Reichenbach recommends the "descriptively simpler" alternative in which "universal forces" do not exist. To be sure, "descriptive simplicity has nothing to do with truth", i.e., has no bearing on the question of whether spacetime has a non-Euclidean structure (1928, 47; 1958, 35).

4.3 Critique of Reichenbachian Metric Conventionalism

In retrospect, it is rather difficult to understand the significance that has been accorded this argument. Carnap, for example, in his "Introductory Remarks" (1958, vii) to the posthumous English translation of this work, singled it out on account of its "great interest for the methodology of physics". Reichenbach himself deemed "the philosophical achievement of the theory of relativity" to lie in this methodological distinction between conventional and factual claims regarding spacetime geometry (1928, 24; 1958, 15), and he boasted of his "philosophical theory of relativity" as an incontrovertible "philosophical result":

> *the philosophical theory of relativity*, i.e., the discovery of the definitional character of the metric in all its details, holds independently of experience….a philosophical result not subject to the criticism of the individual sciences." (1928, 223; 1958, 177)

Yet this result is neither incontrovertible nor an untrammeled consequence of Einstein's theory of gravitation. There is, first of all, the shadowy status accorded to "universal forces". A sympathetic reading (e.g., Dieks (1987)) suggests that the notion serves usefully in mediating between a traditional *a priori* commitment to Euclidean geometry and the view of modern geometrodynamics, where gravitational force is "geometrised away" (see §5). For, as Reichenbach explicitly acknowledged, gravitation is itself a "universal force", coupling to all bodies and affecting them in the same manner (1928, 294-6; 1958, 256-8). Hence the choice recommended by "descriptive simplicity" is merely a stipulation that metrical appliances, regarded as "infinitesimal", be considered as "differentially at rest" in an inertial system (1924, 115; 1969, 147). This is a stipulation that spacetime measurements always take place in regions that are to be considered small Minkowski spacetimes (arenas of gravitation-free physics). By the same token, however, consistency required an admission that "the transition from the special theory to the general one represents merely a renunciation of metrical characteristics" (1924, 115; 1969, 147), or, even more pointedly, that "all the metrical properties of the spacetime continuum are destroyed by gravitational fields" where only topological properties remain (1928, 308; 1958, 268-9). To be sure, these conclusions are supposed to be rendered more palatable in connection with the epistemological reduction of spacetime structures in the causal theory of time.

Despite the influence of this argument on the subsequent generation of philosophers of science, Reichenbach's analysis of spacetime measurement treatment is plainly inappropriate, manifesting a fallacious tendency to view the generically curved spacetimes of general relativity as stiched together from little bits of flat Minskowski spacetimes. Besides being mathematically inconsistent, this procedure

offers no way of providing a non-metaphorical physical meaning for the fundamental metrical tensor $g_{\mu\nu}$, the central theoretical concept of general relativity, nor to the series of curvature tensors derivable from it and its associated affine connection. Since these sectional curvatures at a point of spacetime are empirically manifested and the curvature components can be measured, e.g., as the tidal forces of gravity, they can hardly be accounted as due to conventionally adopted "universal forces". Furthermore, the concept of an "infinitesimal rigid rod" in general relativity cannot really be other than the interim stopgap Einstein recognized it to be. For it cannot actually be "rigid" due to these tidal forces; in fact, the concept of a "rigid body" is already forbidden in special relativity as allowing instantaneous causal actions. Secondly, such a rod must indeed be "infinitesimal", i.e., a freely falling body of negligible thickness and of sufficiently short extension, so as to not be stressed by gravitational field inhomogeneities; just how short depending on strength of local curvatures and on measurement error (Torretti (1983), 239). But then, as Reichenbach appeared to have recognized in his comments about the "destruction" of the metric by gravitational fields, it cannot serve as a coordinately defined general standard for metrical relations. In fact, as Weyl was the first to point out, precisely which physical objects or structures are most suitable as measuring instruments should be decided on the basis of gravitational theory itself. From this enlightened perspective, measuring rods and clocks are objects that are far too complicated. Rather, the metric in the region around any observer O can be empirically determined from freely falling ideally small neutral test masses together with the paths of light rays. More precisely stated, the spacetime metric results from the affine-projective structure of the behavior of neutral test particles of negligible mass and from the conformal structure of light rays received and issued by the observer. (Weyl, 1921) Any purely conventional stipulation regarding the behavior of "measuring rods" as physically constitutive of metrical relations in general relativity is then otiose (Weyl, 1923a; Ehlers, Pirani and Schild (1973)). Alas, since Reichenbach reckoned the affine structure of the gravitational-inertial field to be just as conventional as, on his view, its metrical structure, he was not able to recognize this method as other than an equivalent, but by no means necessarily preferable, account of the empirical determination of the metric through the use of rods and clocks (Coffa, 1979; Ryckman (1994), (1996)).

5. "Geometrization of Physics": Realism and Transcendental Idealism

5.1 Differing Motivations

In the decade or so following the appearance of the general theory of relativity, there was much talk of a "geometrization" of physics (Weyl (1918b), (1919); Haas (1920); Lodge (1921)). While these discussions were largely, and understandably, confined to scientific circles, they nonetheless brought distinctly philosophical issues — of methodology, but also of epistemology and metaphysics — together with technical matters. General relativity revived a geometrizing tendency essentially dormant within physics since the 17th century. In so doing, it opened up the prospect of a "geometrization" of physics, the possibility of finding a unifying representation of all of known physics within a single geometrical theory of the spacetime continuum. Einstein himself, however, was not the first to embark on this audacious quest. Rather he initially followed in the mathematical footsteps of Hermann Weyl, Arthur Stanley

Eddington, and Theodore Kaluza, only gradually (1925) devising the first of his own "homegrown" geometrical "unified field theories". Still, by 1923, Einstein had become the recognized leader of the unification program. (Vizgin (1994), 265)

The first phase of the geometrical unification program essentially ended with Einstein's "distant parallelism" theory of 1928-1931 (1929), perhaps Einstein's final public sensation (Fölsing (1997, 605)). Needless to say, none of these efforts met with success. In a lecture at the University of Vienna on October 14, 1931, Einstein forlornly referred to these failed attempts, each conceived on a different differential geometrical basis, as a "graveyard of dead hopes" (Einstein, 1932). By this time, certainly, the prospects for the geometrical unification program had considerably waned. A consensus emerged among nearly all leading theoretical physicists that while the geometrical unification of the gravitation and electromagnetic fields might be attained in formally different ways, the problem of matter, treated with undeniable empirical success by the new quantum theory, was not to be resolved within the confines of spacetime geometry. In any event, from the early 1930s, any unification program appeared greatly premature, in view of the wealth of data produced by the new physics of the nucleus.

As many will know, the unsuccessful pursuit of the goal of geometrical unification absorbed Einstein, and his various research assistants, for more than three decades, up to Einstein's death in 1955. In the course of it, Einstein's methodology of research diametrically changed. In place of physical or heuristic principles to guide theoretical construction, such as the principle of equivalence, which put him on the path to general relativity, he increasingly relied on considerations of mathematical aesthetics, such as "logical simplicity" and the inevitability of certain mathematical structures under variously adopted constraints. In a talk entitled "On the Method of Theoretical Physics" at Oxford in 1933, the transformation was stated dramatically:

> Experience remains, of course, the sole criterion of the physical utility of a mathematical construction. But the creative principle resides in mathematics. In a certain sense, therefore, I hold it true that pure thought can grasp reality, as the ancients dreamed. (274)

Moreover, the advent and accumulating empirical successes of the new quantum theory did not dislodge Einstein's core metaphysical belief in a physical reality conceived as a continuous "total field" whose components are functions of the spacetime variables, a geometrical conception of physical reality implied, to be sure, by general relativity (e.g., (1950), 348). Yet, whatever may have been Kaluza's philosophical motivations in putting forward his proposal for geometrical unification, neither Einstein's mathematical realism nor his metaphysics guided either Weyl or Eddington, a fact that has often been obscured or ignored in historical treatments. The geometrical unifications of Weyl (1918a,b) and Eddington (1921) were above all explicit attempts to comprehend the nature of physical theory, in the light of general relativity, from systematic epistemological standpoints that were neither positivist nor realist. As such they comprise "early philosophical interpretations" of that theory, although they intertwine philosophy, geometry and physics in a manner unprecedented since Descartes. Before turning attention to their "interpretations", it will be helpful to see how the geometrizing tendency arises within general relativity itself and to note a few details of the geometrical unification program that followed in its wake.

5.2 "Geometrizing" Gravity: the Initial Step

Einstein's so-called "geometrization" of gravitational force in 1915 gave the geometrization program its first, partial, realization as well as its subsequent impetus. In Einstein's theory, the fundamental or "metric" tensor *g* of Riemannian geometry appears in a dual role which thoroughly fuses its geometrical and its physical meanings. As is apparent from the expression for the "interval" between neighboring spacetime events, $ds^2 = g_{\mu\nu}\, dx^\mu\, dx^\nu$ (here, and below there is an implicit summation over repeated upper and lower indices), the metric tensor is at once the geometrical quantity underlying measurable metrical relations of lengths and times. In this role it ties a mathematical theory of events in four-dimensional "curved" spacetime to observations and measurements in space and time. But it is also the "potential" of the gravitational (or "metrical") field whose value, at any point of spacetime, depends, via the Einstein Field Equations (see below), on the presence of physical quantities of mass-momentum-stress in the immediate region. In the new view, the idea of strength of gravitational "force" is replaced by that of degree of "curvature" of spacetime. Such a curvature is manifested, for example, by the "tidal force" of the Earth's gravitational field that occasions two freely falling bodies, released at a certain height and at fixed separation, to approach one another. A freely falling body is no longer to be regarded as moving through space according to the "pull" of an attractive gravitational "force", but simply as tracing out the "laziest" track along the bumps and hollows of spacetime itself. The Earth's mass (or equivalently, energy) determines a certain spacetime curvature and so becomes a source of gravitational action. At the same time, the gross mechanical properties of bodies, comprising all gravitational-inertial phenomena, can be derived as the solution of a single system of generally covariant partial differential equations, the Einstein equations of the gravitational field. According to these equations, spacetime and matter stand in dynamical interaction. One abbreviate way of characterizing the dual role of the $g_{\mu\nu}$ is to say that in the general theory of relativity, gravitation, which includes mechanics, has become "geometrized", i.e., incorporated into the geometry of spacetime.

5.3 Extending "Geometrization"

In making spacetime curvature dependent on distributions of mass and energy, general relativity is indeed capable of encompassing all (non-quantum) physical fields. However, in classical general relativity there remains a fundamental asymmetry between gravitational and non-gravitational fields, in particular, electromagnetism, the only other fundamental physical interaction definitely known at the time. This shows up visibly in one form of the Einstein field equations in which, on the left-hand side, a geometrical object ($G_{\mu\nu}$, the Einstein tensor) built up from the uniquely compatible linear symmetric ("Levi-Civita") connection associated with the metric tensor $g_{\mu\nu}$, and representing the curvature of spacetime, is set identical to a tensorial but non-geometrical phenomenological representation of matter on the right-hand side.

$$G_{\mu\nu} = k\, T_{\mu\nu}, \quad \text{where } G_{\mu\nu} = R_{\mu\nu} - 1/2\, g_{\mu\nu} R$$

The expression on the right side, introduced by a coupling constant, mathematically represents the non-gravitational sources of the gravitational field in a region of spacetime in the form of a stress-energy-

momentum tensor (an "*omnium gatherum*" in Eddington's pithy phrase (1919, 63)). As the geometry of spacetime principally resides on the left-hand side, this situation seems unsatisfactory. Late in life, Einstein likened his famous equation to a building, one wing of which (the left) was built of "fine marble", the other (the right) of "low grade wood" (1936, 311). In its classical form, general relativity accords only the gravitational field a direct geometrical significance; the other physical fields reside *in* spacetime; they are not *of* spacetime.

Einstein's dissatisfaction with this asymmetrical state of affairs was palpable at an early stage and was expressed with increasing frequency beginning in the early 1920s. A particularly vivid declaration of the need for geometrical unification was made in his "Nobel lecture" of July, 1923:

> The mind striving after unification of the theory cannot be satisfied that two fields should exist which, by their nature, are quite independent. A mathematically unified field theory is sought in which the gravitational field and the electromagnetic field are interpreted as only different components or manifestations of the same uniform field,… The gravitational theory, considered in terms of mathematical formalism, i.e. Riemannian geometry, should be generalized so that it includes the laws of the electromagnetic field."(489)

It might be noted that the tacit assumption, evident here, that incorporation of electromagnetism into spacetime geometry requires a generalization of the Riemannian geometry of general relativity, though widely held at the time, is not quite correct (Rainich (1925); Misner and Wheeler (1962); Geroch (1966)).

5.4 A "Pure Infinitesimal Geometry"

Still, it wasn't Einstein, but the mathematician Hermann Weyl who first addressed the asymmetry in 1918 in the course of refashioning Einstein's theory on the preferred epistemological basis of a "pure infinitesimal geometry" *(Reine Infinitesimalgeometrie).* Holding that direct — *evident*, in the sense of Husserlian phenomenology --comparisons of length or duration could be made at neighboring points of spacetime, but not, as the Riemannian geometry of Einstein's theory permitted, "at a distance", Weyl discovered additional terms in his geometry that he identified with the potentials of the electromagnetic field. From these, the electromagnetic field strengths can be immediately derived and so electromagnetism as well as gravitation could be expressed solely within the terms of spacetime geometry. As no other interactions were definitely known to occur, Weyl proudly declared that the concepts of geometry and physics were the same. Hence, everything in the physical world was a manifestation of spacetime geometry.

> (The) distinction between geometry and physics is an error, physics extends not at all beyond geometry: the world is a (3+1) dimensional metrical manifold, and all physical phenomena transpiring in it are only modes of expression of the metric field, …. (M)atter itself is dissolved in "metric" and is not something substantial that in addition exists "in" metric space (1919, 115-16).

By the winter of 1919-1920, for both physical and philosophical reasons (the latter having to do with his conversion to Brouwer's "intuitionist" views about the mathematical continuum, in particular, the continuum of spacetime), Weyl (1920) surrendered the belief, expressed here, that matter, with its corpuscular structure, might be derived within spacetime geometry. Thus he gave up the Holy Grail of the nascent unified field theory program almost before it had begun. Nonetheless, he actively defended his theory well into the 1920s, essentially on the grounds of Husserlian transcendental phenomenology, that his geometry and its central principle, "the epistemological principle of relativity of magnitude" comprised a superior epistemological framework for general relativity. Weyl's postulate of a "pure infinitesimal" non-Riemannian metric for spacetime, according to which it must be possible to independently choose a "gauge" (scale of length or duration) at each spacetime point, met with intense criticism. No observation spoke in favor of it; to the contrary, Einstein pointed out that according to Weyl's theory, the atomic spectra of the chemical elements should not be constant, as indeed they are observed to be. Although Weyl responded to this objection forcefully, and with some subtlety (Weyl, 1923a), he was able to persuade neither Einstein, nor any other leading relativity physicist, with the exception of Eddington. However, the idea of requiring "gauge invariance" of fundamental physical laws was revived and vindicated by Weyl himself in a different form later on (Weyl (1929);see also O'Raifeartaigh (1997)).

5.5 Eddington's "World Geometry"

Despite Weyl's failure to win many friends for his theory, his guiding example of unification launched the geometrical program of "unified field theory", initiating a variety of efforts, all aimed at finding a suitable generalization of the Riemannian geometry of Einstein's theory to encompass as well non-gravitational physics (Vizgin (1994), ch.4). In December, 1921, the Berlin Academy published Theodore Kaluza's novel proposal for unification of gravitation and electromagnetism upon the basis of a five-dimensional Riemannian geometry. But earlier that year, in February, came Arthur Stanley Eddington's further generalization of Weyl's four-dimensional geometry, wherein the sole primitive geometrical notion is the non-metrical comparison of direction or orientation at the same or neighboring points. In Weyl's geometry the magnitude of vectors at the same point, but pointing in different directions, might be directly compared to one another; in Eddington's, comparison was immediate only for vectors pointing in the same direction. His "theory of the affine field" included both Weyl's geometry and the semi-Riemannian geometry of Einstein's general relativity as special cases. Little attention was paid however, to Eddington's claim, prefacing his paper, that his objective had not been to "seek (the) unknown laws (of matter)" as befits a unified field theory. Rather it lay "in consolidating the known (field) laws" wherein "the whole scheme seems simplified, and new light is thrown on the origin of the fundamental laws of physics" (1921, 105).

Eddington was persuaded that Weyl's "principle of relativity of length" was "an essential part of the relativistic conception", a view he retained to the end of his life (e.g., (1939, 28)). But he was also convinced that the largely antagonistic reception accorded Weyl's theory was due to its confusing formulation. The flaw lay in Weyl's failure to make transparently obvious that his locally scale invariant ("pure infinitesimal") "world geometry" was not the physical geometry of actual spacetime, but an entirely mathematical geometry inherently serving to specify the ideal of an observer-independent

external world. To remedy this, Eddington devised a general method of deductive presentation of field physics in which "world geometry" is developed mathematically as conceptually separate from physics. A "world geometry" is a purely mathematical geometry the derived objects of which possess only the structural properties requisite to the ideal of a completely impersonal world; these are objects, as he wrote in *Space, Time and Gravitation* (1920), a semi-popular best-seller, represented "from the point of view of no one in particular". Naturally, this ideal had changed with the progress of physical theory. In the light of relativity theory, such a world is indifferent to specification of reference frame and, after Weyl, of gauge of magnitude (scale). A "world geometry" is not the physical theory of such a world but a framework or "graphical representation" in whose terms existing physical theory might be displayed, essentially by the mathematical identification of known tensors of the existing physical laws of gravitation and electromagnetism, with tensors of the world geometry. Such a geometrical representation of physics cannot really be said to be "right" or "wrong", for it only implements, if it can, current ideas governing the conception of objects and properties of an impersonal objective external world. But when existing physics, in particular, Einstein's theory of gravitation, is set in the context of Eddington's world geometry, it yields a surprising consequence: The Einstein law of gravitation appears as a definition! In the form $R^{\mu\nu} = 0$ it defines what in the "world geometry" appears to the mind as "vacuum" while in the form of the Einstein field equation noted above, it defines what is there encountered by the mind as "matter". This result is what was meant by his stated claim of throwing "new light on the origin of the fundamental laws of physics". Eddington's notoriously difficult and opaque later works (1936), (1946), took their inspiration from this argumentation in attempting to carry out a similar, but algebraic, program of deriving fundamental physical laws, and the constants occurring in them, from epistemological principles.

5.6 Meyerson on "Pangeometrism"

Within physics the idealist currents lying behind the "world geometries" of Weyl and Eddington were largely ignored, whereas within philosophy, with the notable exception of Émile Meyerson's *La Déduction Relativiste* (1925),most philosophers lacked the tools to connect these readily discernible currents with their geometrical theories. Meyerson, who had no doubt of the basic realist impetus of science, carefully distinguished Einstein's "rational deduction of the physical world" from the geometrical unifications of gravitation and electromagnetism of Weyl and Eddington. These theories, as affirmations of a complete *panmathematicism*, or rather of a *pangeometrism* (§§ 157-58), were compared to the rational deductions of Hegel's *Logic*. That general relativity succeeded in partly realizing Descartes' program of reducing the physical to the spatial through geometric deduction, is due to the fact that Einstein "followed in the footsteps" of Descartes, not Hegel (§133). But *pan-geometrism* is also capable of overreaching itself and this is the transgression committed by Weyl and Eddington. Weyl in particular is singled out for criticism for seemingly to have reverted to Hegel's monistic idealism, and so to be subject to its fatal flaw. In regarding nature as completely intelligible, Weyl had abolished the thing-in-itself and so promoted the identity of self and non-self, the great error of the *Naturphilosophien*.

Though he had "all due respect to the writings of such distinguished scientists" as Weyl and Eddington, Meyerson took their overt affirmations of idealism to be misguided attempts "to associate themselves with a philosophical point of view that is in fact quite foreign to the relativistic doctrine" (§150). That

"point of view" is in fact two distinct species of transcendental idealism. It is above all "foreign" to relativity theory because Meyerson cannot see how it is possible to "reintegrate the four-dimensional world of relativity theory into the self". After all, Kant's own argument for Transcendental Idealism proceeded "in a single step", in establishing the subjectivity of the space and time of "our naïve intuition". But this still leaves "the four dimensional universe of relativity independent of the self". Any attempt to "reintegrate" four-dimensional spacetime into the self would have to proceed at a "second stage" where, additionally, there would be no "solid foundation" such as spatial and temporal intuition furnished Kant at the first stage. Perhaps, Meyerson allowed, there is indeed "another intuition, purely mathematical in nature", lying behind spatial and temporal intuition, and capable of "imagining the four-dimensional universe, to which, in turn, it makes reality conform". This would make intuition a "two-stage mechanism". While all of this is not "inconceivable", it does appear, nonetheless, "rather complex and difficult if one reflects upon it". In any case, this is likely to be unnecessary, for considering the matter "with an open mind",

> one would seem to be led to the position of those who believe that relativity theory tends to destroy the concept of Kantian intuition (§§ 151-2).

Meyerson had come right up to the threshold of grasping the Weyl-Eddington geometric unification schemes in something like the sense in which they were intended. The stumbling block for him, and for others, is the conviction that transcendental idealism can be supported only from an argument about the nature of intuition, and intuitive representation. To be sure, the geometric framework for Weyl's construction of the objective four-dimensional world of relativity is based upon the *Evidenz* available in "essential insight", which is limited to the simple linear relations and mappings in what is basically the tangent vector space to a point in a manifold. Thus in Weyl's differential geometry there is a fundamental divide between integrable and non-integrable relations of comparison. The latter are primitive and epistemologically privileged, but nonetheless not justified until it is shown how the infinitesimal homogenous spaces, corresponding to the "essence of space as a form of intution", are compatible with the large-scale inhomogenous spaces (spacetimes) of general relativity. And this required not a philosophical argument about the nature of intution, but one formulated in group-theoretic *conceptual* form. (Weyl, 1923a,b). Eddington, on the other hand, without the cultural context of Husserlian phenomenology or indeed of philosophy generally, jettisoned the intuitional basis of transcendental idealism altogether, as if unaware of its prominence. Thus he sought a superior and completely general *conceptual* basis for the objective four-dimensional world of relativity theory by constituting that world within a geometry (its "world structure" (1923)) based upon a non-metrical affine (i.e., linear and symmetric) connection. He was then free to find his own way to the empirically confirmed integrable metric relations of Einstein's theory without being hampered by the conflict of a "pure infinitesimal" metric with the observed facts about rods and clocks.

5.7 "Structural Realism"?

It has been routinely assumed that all the attempts at a "geometrization of physics" in the early unified field theory program shared something of Einstein's hubris concerning the ability of mathematics to "grasp" the fundamental structure of the external world. The geometrical unified field theory program

thus appears to be inseparably stitched to a form of scientific realism, recently termed "structural realism", with perhaps even an inspired turn toward Platonism. According to "structural realism", whatever the "nature" of the fundamental entities comprising the physical world, only their "structure" can be known as that structure is represented in the equations of the theory. The sole ontological continuity across changes in fundamental physical theory is a continuity of structure, as the equations of the earlier theory can be derived,say as limit cases, from those of the later. Geometrical unification theories seems tailored for this kind of realism. For if a geometrical theory is taken to give a true or approximately true representation of the physical world, what is geometrically represented has the definite structure of the fundamental geometrical relations. But for Weyl and Eddington, geometrical unification was not, nor could be, such a representation, for essentially the reasons articulated two decades before by Poincaré (1906,14):

> Does the harmony the human intelligence thinks it discovers in nature exist outside of this intelligence? No, beyond doubt, a reality completely independent of the mind which conceives it, sees or feels it, is an impossibility. A world as exterior as that, even if it existed, would for us be forever inaccessible. But what we call objective reality is, in the last analysis, what is common to many thinking beings, and could be common to all; this common part,...,can only be the harmony expressed by mathematical laws. It is this harmony then which is the sole objective reality....

In Weyl and Eddington, geometrical unification was an attempt to cast the "harmony" of the Einstein theory of gravitation in a new epistemological and explanatory light, by displaying the great field laws of gravitation and electromagnetism within the common frame of a geometrically represented objective reality. Their unorthodox manner of philosophical argument, cloaked, perhaps necessarily, in the language of differential geometry, has tended to conceal or obscure conclusions about the significance of a "geometrized physics" that push in considerably different directions from either instrumentalism or scientific realism.

Equivalence of Mass and Energy

Einstein correctly described the equivalence of mass and energy as "the most important upshot of the special theory of relativity" (Einstein, 1919), for it is more than a mere curiosity of physics. According to Einstein's famous equation $E = mc^2$, the energy (E) of a body is numerically equal to the product of its mass (m) and the speed of light (c) squared. It is customary to refer to this result as "the equivalence of mass and energy," or simply "mass-energy equivalence," because one can choose units in which $c = 1$, and hence $E = m$. An important consequence of $E = mc^2$ is that a change in the rest-energy of a body is accompanied by a corresponding change to its inertial mass. (This is discussed further in Section 1.) This has led many philosophers to argue that mass-energy equivalence has profound consequences for ontology, the philosophical study of what there is. There are two main philosophical interpretations of $E = mc^2$. The first is that mass-energy equivalence teaches us that "mass" and "energy" designate the same *property* of physical systems. This is the weaker of the two interpretations because no further ontological claims are made. The second interpretation is that $E = mc^2$ entails that there is only one sort of fundamental *stuff* in the world. (This is discussed further in Section 2.) Recently, the history of $E = mc^2$ has also attracted the attention of some philosophers. This is primarily, though not exclusively, because this history shows that $E = mc^2$ is a direct consequence of changes to the structure of spacetime brought about by Special Relativity. (This is discussed further in Section 3.)

1. Mass-Energy Equivalence: The Result

The equation $E=mc^2$ has two distinct physical consequences. To see this, one needs first to distinguish

between a body's rest-mass and its relativistic mass. In Newtonian physics, the inertial mass of a body is a measure of that body's resistance to acceleration. This is the notion of mass one uses in everyday life when one talks about, for example, 1 kg. of salt. Furthermore, in Newtonian physics, the inertial mass of a body is independent of its relative state of motion. Because this is no longer the case in relativistic physics, one can identify two notions of mass in Special Relativity (SR). The *rest-mass* of a body is the inertial mass of that body when it is at rest relative to an inertial frame. The term m in the equation $E=mc^2$ does *not* represent rest-mass; it represents *relativistic mass*, which is the inertial mass of a body when it is in a state of motion relative to an inertial frame. If we use m_o to designate the rest-mass of a body, then we can re-write Einstein's equation in the following way:

$$E = mc^2 = m_o \gamma(v) c^2, \text{ where } \gamma(v) = \frac{1}{\sqrt{1-\frac{v^2}{c^2}}} \text{ is the "Lorentz Factor".}$$

These equations entail that:

> **(I)** In the frame of reference in which a body is at rest, its energy (in this case called the *rest-energy*) is equal to the product of its rest-mass m_o and the speed of light squared. This is because in this case $v = 0$, so the Lorentz factor is one.
>
> **(II)** In a frame of reference in which a body moves with velocity v, the energy of the body is equal to the product of its rest-mass, the speed of light squared, and the Lorentz factor.

From **(I)** it follows that if there is a change in the rest-energy of a body, there must be a corresponding change in its rest-mass. For example, if a body is heated, and thereby absorbs a small amount of energy ΔE (as measured in the frame of reference in which the body is at rest), its rest-mass will increase by a very small amount equal to $\Delta E/c^2$. This increase is tiny because of the high numerical value of the speed of light. Indeed, for mid-sized objects, such an increase in mass would be too small to measure with even the most accurate balance. For example, if a 1 kg block of gold is heated so that its temperature increases by 10 °C, then its mass could increase by as much as 1.4×10^{-14} kg; a cube of gold of this additional tiny mass would have sides smaller than one one-thousandths of a millimeter. Similarly, if a body emits an amount of energy ΔE, say in the form of light or heat, its rest-mass will decrease by a tiny amount $\Delta E/c^2$. In both cases, the important and novel claim made by SR is that the inertial mass of a body can change depending on whether it absorbs or emits energy.

(I) also entails that there are physical interactions in which masses no longer combine by simple addition, as they do in pre-relativistic physics. For example, suppose two bodies *A* and *B* collide to produce a single, more massive body *AB*. Suppose further that a net amount of energy *E* is emitted in this inelastic collision, say in the form of heat. **(I)** entails that the rest-mass of *AB* will be *less* than the rest-mass of *A* plus the rest-mass of *B* by an amount equal to E/c^2. This stands in sharp contrast to the pre-relativistic

prediction that the rest-mass of *AB* will be *equal* to the rest-mass of *A* plus the rest-mass of *B*. So, for example, suppose a meteor (*A*) struck the earth (*B*). After the crash, the earth (*AB*) would have a mass that is a tiny bit less than the mass of the meteor plus the mass of the earth prior to the crash. This is because during the collision the meteor loses part of its kinetic energy as heat radiation. This energy loss corresponds to a loss of mass. It is worth emphasizing that, according to SR, it is the *inertial* mass of bodies that is no longer simply added in collisions such as these. In other words, SR predicts that the resulting body *AB* will resist acceleration a tiny bit less than one would have predicted according to pre-relativistic physics. There is an analogous result for cases where a single body disintegrates into two or more bodies.

These consequences of **(I)** also illustrate how the classical conservation principles are modified by SR. According to Newtonian physics, all physical interactions are separately governed by the principles of conservation of mass and conservation of energy. So, for example, according to pre-relativistic physics the mass of the block of gold discussed above must remain the same as it is heated. However, as we have seen, this is not the case in relativistic physics, because the energy absorbed by the block of gold contributes to an increase in its rest-mass. Similarly, Newtonian physics predicts that mass is conserved when the meteor crashes into the earth in the above example. However, according to relativistic physics, some of the mass is radiated away as energy in the form of heat. In both of these examples, it is the total mass *and* energy of the entire system that is conserved in these interactions. In general, in SR physical interactions no longer satisfy the two classical conservation principles separately. Instead, these two principles are fused into a single principle: the principle of conservation of mass-energy. It is these consequences of **(I)**, and indirectly the fusing of the two classical conservation principles, that have motivated different philosophical interpretations of $E=mc^2$ (see Section 2, Philosophical Interpretations of Mass-Energy Equivalence).

From **(II)** it follows that no bounded amount of energy is sufficient to accelerate a body to the speed of light. This is because as the speed of a body approaches the speed of light its relativistic mass increases without bound. But this means that the body's resistance to acceleration, as measured in the inertial frame relative to which it is moving, also increases without bound. In practice, this means that it takes more and more energy to achieve proportionally smaller increases in the speed of a body. For example, suppose an electron requires an amount of energy E to reach 50% of the speed of light. The electron requires twice that amount of energy to reach 90% of the speed of light, roughly six times E to reach 99% of the speed of light, and nearly two hundred times E to reach 99.999% of the speed of light! This consequence of $E=mc^2$ is thus crucial in the design and operation of particle accelerators, and it is often emphasized in the popular media (e.g., in popular science books and films). However, its philosophical import is relatively minor because the increase in relativistic mass does not result in a change to the body. In the frame of reference in which the body is at rest, its inertial mass continues to be m_o.

A common misconception surrounding $E = mc^2$ is that it entails that the entire rest-mass of a body can become energy. Strictly speaking, mass-energy equivalence only entails that a *change* in the rest-energy of a body is invariably accompanied by a corresponding *change* in the rest-mass of the body. For example, a body may lose a bit of its mass because it radiates a bit of energy. The stronger claim that a

body may lose *all* of its rest-mass as it radiates energy is *not* a consequence of SR. However, this stronger claim is very well confirmed by experiments in atomic physics. Many particle-antiparticle collisions have been observed, such as collisions between electrons and positrons, where the entire mass of the particles is radiated away as energy in the form of light. Nevertheless, SR leaves open the possibility that a form of matter exists whose mass cannot become energy. This is significant because it emphasizes that mass-energy equivalence is not a consequence of a theory of matter; it is instead a direct consequence of changes to the structure of spacetime imposed by SR (see Section 3, Derivations of Mass-Energy Equivalence: History).

2. Philosophical Interpretations of Mass-Energy Equivalence

Philosophical interpretations of mass-energy equivalence can be classified into two main groups. Interpretations in the first group, such as Eddington's (1929), and more recently Torretti's (1983), regard the terms "mass" and "energy" as designating *properties* of physical systems. According to these interpretations, $E = mc^2$ teaches us that properties hitherto regarded as distinct are actually the same. For example, Eddington states that "it seems very probable that mass and energy are two ways of measuring what is essentially the same thing, in the same sense that the parallax and distance of a star are two ways of expressing the same property of location" (1929, p. 146). According to Eddington, the distinction between mass and energy is artificial. We treat mass and energy as different properties of physical systems because we routinely measure them using different units. However, one can measure mass and energy using the *same* units by choosing units in which c =1, i.e., units in which distances are measured in units of time (e.g., light-years). Once we do this, Eddington claims, the distinction between mass and energy disappears.

Torretti (1983) argues along similar lines when he responds to the opposing view, which is held by a minority (e.g., Bunge, 1967; Sachs, 1981). This minority holds that the numerical equivalence of mass and energy is not sufficient to conclude that the two properties are the same. However, according to Torretti, "If a kitchen refrigerator can extract mass from a given jug of water and transfer it by heat radiation or convection to the kitchen wall behind it, a trenchant metaphysical distinction between the mass and the energy of matter does seem far fetched" (1983, p. 307, fn. 13). Like Eddington, Torretti points out mass and energy seem to be different properties because they are measured in different units. But the units of mass and energy are different only if one uses different units for space and time, which one need not do. For Torretti, the apparent difference between mass and energy is thus an illusion that arises from "the convenient but deceitful act of the mind by which we abstract time and space from nature" (1983, p. 307, fn. 13). Interpretations such as Torretti's and Eddington's draw no further ontological conclusions from mass-energy equivalence beyond the claim that the two properties are the same. For example, neither Eddington nor Torretti make any explicit claim concerning whether properties are best understood as universals, or whether one ought to be a realist about such properties.

Interpretations in the second group, such as Zahar's (1984), Einstein and Infeld's (1938), and Russell's

(1915, 1948), regard "mass" as a measure of the quantity of matter and "energy" as a measure of the quantity of energy. Thus, these interpretations regard "mass" and "energy" as the representatives, within physical theory, of stuff in the world. According to these interpretations, the philosophical lesson of $E = mc^2$ is that we should no longer regard the world as consisting of two types of stuff: matter and energy. Instead, the world is composed of only one type of fundamental stuff. For example, According to Zahar, energy in pre-relativistic physics occupies a distinct "ontological level" from matter primarily because the former is regarded as dependent on the latter, but not *vice versa*. In relativistic physics, however, Einstein's famous equation shows that these two ontological levels are in fact identical. According to Zahar, Einstein showed "that ‘energy’ and ‘mass’ *could* be treated as two names for the same basic entity. The stuff which appears to the senses as hard extended substance and the quantity of energy which characterises a process are in fact one and the same thing" (1989, p. 262). For Zahar, the apparent difference between mass and energy arises from the contingent fact that our senses perceive mass and energy differently. On this reading, mass-energy equivalence has the metaphysical implication that what is real, "is no longer the familiar hard substance but a new entity which can be interchangeably called matter or energy" (1989, p. 263). Thus, Zahar holds that the fundamental stuff of physics is a sort of "I-know-not-what" that we can call either "mass" or "energy."

Einstein and Infeld (1938) hold a slightly different version of this interpretation. They claim that mass-energy equivalence implies that we can no longer distinguish between "matter" and "the field". Einstein and Infeld (1938) argue that in pre-relativistic physics there are physical criteria for distinguishing matter and field since matter has mass but fields do not. Hence, there is a qualitative difference between matter and fields, and so it is reasonable to adopt an ontology containing both. However, the equivalence of mass and energy entails that "matter represents vast stores of energy and that energy represents matter" (1938, p. 242). Consequently, Einstein and Infeld argue, the distinction between matter and field is no longer a qualitative one in relativistic physics. Instead, it is merely a quantitative difference, since "matter is where the concentration of energy is great, field where the concentration of energy is small"(1938, p. 242). Thus, mass-energy equivalence entails that we should adopt an ontology consisting only of fields.

Among philosophers, Russell interprets mass-energy equivalence in a similar fashion to Einstein and Infeld. According to Russell, "a unit of matter tends more and more to be something like an electromagnetic field filling all space, though having its intensity in a small region" (1915, p. 121). In his later work, Russell continues to hold this view. For example, in *Human Knowledge, Its Scope and Limits*, he points out that "atoms" are merely small regions in which there is a great deal of energy. Furthermore, these regions are precisely the regions where one would have said, in pre-relativistic physics, that there was matter. For Russell, these considerations suggest that "mass is only a form of energy, and there is no reason why matter should not be dissolved into other forms of energy. It is energy, not matter, that is fundamental in physics" (1948, p. 291). Russell is not claiming, as Zahar does, that there is one unknown type of stuff that we can call either "mass" or "energy". Instead, Russell is proposing that mass is *reducible* to energy in the sense that the world consists only of energy. Thus, for Russell, "mass" and "matter" are otiose in modern physics. Several physicists have held a similar position, though this view is less common now. For example, after a discussion particle-antiparticle annihilation experiments in 1951, Wolfgang Pauli states: "Taking the existence of all these transmutations into account, what remains of the old idea of matter and of substance? The answer is energy. This is the true substance, that which is

conserved; only the form in which it appears is changing" (1951, p. 31).

Despite the marked difference in the ontological claims made by the two groups of interpretations, there is one significant similarity. All interpretations implicitly claim that mass-energy equivalence changes our knowledge concerning the extensions of the concepts "mass" and "energy". In pre-relativistic physics, the terms "mass" and "energy" had different extensions and intensions. Relativistic physics teaches us that the extension of the two terms is actually the same. This is analogous to the discovery that the referents of "the morning star" and "the evening star" are the same. We can push the analogy a bit further. Just as it is possible to verify empirically that the planet Venus is the referent of both "the morning star" and "the evening star," it is possible to verify empirically that the extensions of "mass" and "energy" are the same. (See Section 4, Experimental Verification of Mass-Energy Equivalence.) From this perspective, the various interpretations of mass-energy equivalence disagree only about what kinds of things the terms "mass" and "energy" designate.

3. Derivations of Mass-Energy Equivalence: History

Einstein first derived mass-energy equivalence from the principles of SR in a small article titled "Does the Inertia of a Body Depend Upon Its Energy Content?" (1905b). This derivation, along with others that followed soon after (e.g., Plank (1906), Von Lau (1911)), uses Maxwell's theory of electromagnetism. (See Subsection 3.1, Derivations of $E = mc^2$ that Use Maxwell's Theory.) However, as Einstein later observed (1935), mass-energy equivalence is a result that should be independent of any theory that describes a specific physical interaction. This is the main reason that led physicists to search for "purely dynamical" derivations, i.e., derivations that invoke only mechanical concepts such as "energy" and "momentum", and the principles that govern them. (See Subsection 3.2, Purely Dynamical Derivations of $E = mc^2$.)

3.1 Derivations of $E = mc^2$ that Use Maxwell's Theory

Einstein's original derivation of mass-energy equivalence is the best known in this group. Einstein begins with the following thought-experiment: a body at rest (in some inertial frame) emits two pulses of light of equal energy in opposite directions. Einstein then analyzes this "act of emission" from another inertial frame, which is in a state of uniform motion relative to the first. In this analysis, Einstein uses Maxwell's theory of electromagnetism to calculate the physical properties of the light pulses (such as their intensity) in the second inertial frame. By comparing the two descriptions of the "act of emission", Einstein arrives at his celebrated result: "the mass of a body is a measure of its energy-content; if the energy changes by L, the mass changes in the same sense by $L/9 \times 10^{20}$, the energy being measured in ergs, and the mass in grammes" (1905b, p. 71). A similar derivation using the same thought experiment but appealing to the Doppler effect was given by Langevin (1913) (see the discussion of $E = mc^2$ in Fox (1965)).

Some philosophers and historians of science claim that Einstein's first derivation is fallacious. For example, in *The Concept of Mass*, Jammer says: "It is a curious incident in the history of scientific

thought that Einstein's own derivation of the formula $E = mc^2$, as published in his article in *Annalen der Physik*, was basically fallacious. . . the result of a *petitio principii*, the conclusion begging the question" (Jammer, 1961, p. 177). According to Jammer, Einstein implicitly assumes what he is trying to prove, viz., that if a body emits an amount of energy L, its inertial mass will decrease by an amount $\Delta m = L/c^2$. Jammer also accuses Einstein of assuming the expression for the relativistic kinetic energy of a body. If Einstein made these assumptions, he would be guilty of begging the question. Recently, however, Stachel and Torretti (1982) have shown convincingly that Einstein's (1905b) argument is sound. They note that Einstein indeed derives the expression for the kinetic energy of an "electron" (i.e., a structureless particle with a net charge) in his earlier (1905a) paper. However, Einstein nowhere uses this expression in the (1905b) derivation of mass-energy equivalence. Stachel and Torretti also show that Einstein's critics overlook two key moves that are sufficient to make Einstein's derivation sound, since one need not assume that $\Delta m = L/c^2$.

Einstein's further conclusion that "the mass of a body is a measure of its energy content" (1905b, p. 71) does not, strictly speaking, follow from his argument. As Torretti (1983) and other philosophers and physicists have observed, Einstein's (1905b) argument allows for the possibility that once a body's energy store has been entirely used up (and subtracted from the mass using the mass-energy equivalence relation) the remainder is not zero. In other words, it is only an hypothesis in Einstein's (1905b) argument, and indeed in all derivations of $E = mc^2$ in SR, that no "exotic matter" exists that is *not* convertible into energy (see Ehlers, Rindler, Penrose, (1965) for a discussion of this point). However, particle-antiparticle anihilation experiments in atomic physics, which were first observed decades after 1905, strongly support "Einstein's dauntless extrapolation" (Torretti, 1983, p. 112).

3.2 Purely Dynamical Derivations of $E = mc^2$

Purely dynamical derivations of $E = mc^2$ typically proceed by analyzing an inelastic collision from the point of view of two inertial frames in a state of relative motion (the centre-of-mass frame, and an inertial frame moving with a relative velocity v). One of the first papers to appear following this approach is Perrin's (1932). According to Rindler and Penrose (1965), Perrin's derivation was based largely on Langevin's "elegant" lectures, which were delivered at the College de France in Zurich around 1922. Einstein himself gave a purely dynamical derivation (Einstein, 1935), though he nowhere mentions either Langevin or Perrin. The most comprehensive derivation of this sort was given by Ehlers, Rindler and Penrose (1965). More recently, a purely dynamical version of Einstein's original (1905b) thought experiment, where the particles that are emitted are not photons, has been given by Mermin and Feigenbaum (1990).

Derivations in this group are distinctive because they demonstrate that mass-energy equivalence is a consequence of the changes to the structure of spacetime brought about by SR. The relationship between mass and energy is independent of Maxwell's theory or any other theory that describes a specific physical interaction.We can get a glimpse of this by noting that to derive $E = mc^2$ by analyzing a collision, one must first define relativistic momentum ($\mathbf{p}_{rel}$) and relativistic kinetic energy (T_{rel}), since one cannot use

the old Newtonian notions of momentum and kinetic energy. In Einstein's own purely dynamical derivation (1935), more than half of the paper is devoted to finding the mathematical expressions that define $\mathbf{p}_{rel}$ and T_{rel}. This much work is required to arrive at these expressions for two reasons. First, the changes to the structure of spacetime must be incorporated into the definitions of the relativistic quantities. Second, $\mathbf{p}_{rel}$ and T_{rel} must be defined so that they reduce to their Newtonian counterparts in the appropriate limit. This last requirement ensures, in effect, that SR will inherit the empirical success of Newtonian physics. Once the definitions of $\mathbf{p}_{rel}$ and T_{rel} are obtained, the derivation of mass-energy equivalence is straight-forward. (For a more detailed discussion of Einstein's (1935), see Flores, (1998).)

4. Experimental Verification of Mass-Energy Equivalence

Cockcroft and Walton (1932) are routinely credited with the first experimental verification of mass-energy equivalence. Einstein (1905b) had conjectured that the equivalence of mass and energy could be tested by "weighing" an atom before and after it undergoes radioactive decay. But there was no way of performing this experiment or another experiment that would directly confirm mass-energy equivalence at the time. Technological developments allowed Cockcroft and Walton to take a different approach. They studied the bombardment of a lithium atom (Li) by a proton (p), which produces two alpha particles (α). This reaction is symbolized by the following equation:

$$p + Li = 2\alpha$$

In this reaction, there is a *decrease* in the total rest-mass as the reaction proceeds from left to right: the total rest-mass of proton and the Lithium atom is greater than the total rest-mass of the two alpha particles. Furthermore, there is also an *increase* in the total kinetic energy: the kinetic energy of the proton is less than the total kinetic energy of the two alpha particles. (One only considers the kinetic energy of the proton because the Lithium atom is considered at rest, and hence has zero kinetic energy.) Cockcroft and Walton were able to measure the kinetic energies of the incident proton and the out-going alpha particles very precisely. They found that the decrease in rest-mass corresponds to the increase in kinetic energy according to Einstein's famous equation $E = mc^2$ (to an accuracy of better than 1%). Hence, the total mass *and* energy of the entire system is conserved.

Space and Time: Inertial Frames

A “frame of reference” is a standard relative to which motion and rest may be measured; any set of points or objects that are at rest relative to one another enables us, in principle, to describe the relative motions of bodies. A frame of reference is therefore a purely kinematical device, for the geometrical description of motion without regard to the masses or forces involved. A dynamical account of motion leads to the idea of an “inertial frame,” or a reference frame relative to which motions have distinguished dynamical properties. For that reason an inertial frame has to be understood as a spatial reference frame together with some means of measuring time, so that uniform motions can be distinguished from accelerated motions. The laws of Newtonian dynamics provide a simple definition: an inertial frame is a reference-frame with a time-scale, relative to which the motion of a body not subject to forces is always rectilinear and uniform, accelerations are always proportional to and in the direction of applied forces, and applied forces are always met with equal and opposite reactions. It follows that, in an inertial frame, the center of mass of a system of bodies is always at rest or in uniform motion. It also follows that any other frame of reference moving uniformly relative to an inertial frame is also an inertial frame. For example, in Newtonian celestial mechanics, taking the “fixed stars” as a frame of reference, we can determine an (approximately) inertial frame whose center is the center of mass of the solar system; relative to this frame, every acceleration of every planet can be accounted for (approximately) as a gravitational interaction with some other planet in accord with Newton’s laws of motion.

This appears to be a simple and straightforward concept. By inquiring more narrowly into its origins and meaning, however, we begin to understand why it has been an ongoing subject of philosophical concern. It originated in a profound philosophical consideration of the principles of relativity and invariance in the context of Newtonian mechanics. Further reflections on it, in different theoretical contexts, had extraordinary consequences for 20th-century theories of space and time.

---

1. Relativity and Reference Frames in Classical Mechanics

1.1 The Origins of Galilean Relativity

The term “reference frame” was coined in the 19th century, but it has a long prehistory, beginning, perhaps, with the emergence of the Copernican theory. The significant point was not the replacement of the earth by the sun as the center of all motion in the universe, but the recognition of both the earth and the sun as merely possible points of view from which the motions of the celestial bodies may be described. This implied that the basic task of Ptolemaic astronomy -- to represent the planetary motions by combinations of circular motions -- could take any point to be fixed, and that, as Copernicus suggested in the opening arguments of “On the revolutions of the heavenly spheres,” the choice of any particular point required some justification on other than astronomical grounds. As the basic programme of Ptolemy and Copernicus gave way to that of early classical mechanics, this equivalence of points of view was made more precise and explicit. Galileo demonstrated that the Copernican view does not contradict our experience of a seemingly stable earth, through a principle that, in the precise form that it takes in Newtonian mechanics, has become known as the “principle of Galilean relativity”: mechanical experiments will have the same results in a system in uniform motion that they have in a system at rest. Therefore the experiments claimed as evidence against Copernicus -- e.g., that a stone dropped from a tower falls to the base of the tower, instead of being left behind -- would happen just as they do whether the earth were moving or not, provided that the motion is sufficiently uniform. See Figure 1.

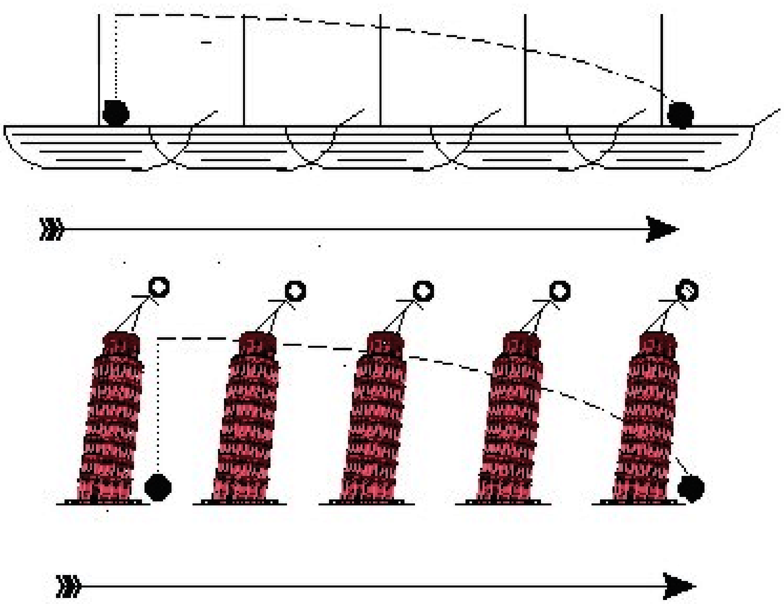

Figure 1: Galileo’s Argument
If the earth is rotating sufficiently uniformly, a stone dropped from the tower will fall straight to the base, just as a stone dropped from the mast of a uniformly moving ship will fall to the foot of the mast. In both cases the stone’s vertical motion will be smoothly composed with its horizontal motion. Hence a sufficiently uniform motion will be indistinguishable from rest.

1.2 Philosophical Controversy Over Absolute and Relative Motion

Leibniz, later, articulated a more general “equipollence of hypotheses”: in any system of interacting bodies, any hypothesis that any particular body is at rest is equivalent to any other. Therefore neither Copernicus’ nor Ptolemy’s view can be true -- though one may be judged simpler than the other -- because both are merely possible hypothetical interpretations of the same relative motions. This principle clearly defines (what we would call) a set of reference frames, differing in their arbitrary choices of a resting point or origin, but agreeing on the relative positions of bodies at any moment and their changing relative distances through time.

For Leibniz and many others, this general equivalence was a matter of philosophical principle, founded in the metaphysical conviction that space itself is nothing more than an abstraction from the geometrical relations among bodies. In some form or other it was a widely shared tenet of the 17th-century “mechanical philosophy”. Yet it was flatly incompatible with physics as Leibniz himself, and the other “mechanists,” actually conceived it. For the basic program of mechanical explanation depended essentially on the concept of

a privileged state of motion, as expressed in the assumption that bodies maintain a state of rectilinear motion until acted upon by an external cause. Thus their fundamental conception of force, as the power of a body to change the state of another, likewise depended on this notion of a privileged state. This dependence was clearly exhibited in the vortex theory of planetary motion, in which every orbit was explained by the balance between the planet's inherent centrifugal tendency (its tendency to follow the tangent to the orbit) and the pressure of the surrounding medium.

For this reason, the notion of a dispute between "relativists" or "relationists" and "absolutists" or "substantivalists", in the 17th century, is a drastic oversimplification. Newton, in his controversial Scholium on space, time, and motion, was not merely asserting that motion is absolute in the face of the mechanists' relativist view; he was arguing that a conception of absolute motion was already implicit in the views of his opponents -- that it was implicit in their conception, which he largely shared, of physical cause and effect. The general equivalence of reference-frames was implicitly denied by a physics that understood forces as powers to change the states of motion of bodies.

Newton therefore held that physics required the conception of absolute space, a distinguished frame of reference relative to which bodies could be said to be truly moving or truly at rest. Assuming, as both Newton and Leibniz did, that states of motion could be distinguished by their causes and effects, the distinguished status of this frame of reference is physically well founded -- and metaphysically well-founded for a metaphysics that, like Newton's or Leibniz's, takes force to be a well-founded notion. On Leibniz's conception of force, in particular, a given force is required to generate *or to maintain* a given velocity -- for objects "passively" resist motion, but maintain their states of motion only by "active" force -- so that, on dynamical grounds, "every body truly does have a certain amount of motion, or, if you will, force." This implies that there is in principle a distinguished frame of reference in which the velocities of bodies correspond to their true velocities, i.e. to the amounts of moving force that they truly possess, and it implies that in any frame that is in motion relative to this one, bodies will not have their true velocities. In short, such a conception of force, if it could be applied physically, would give a precise physical application of Newton's conception of absolute space.

1.3 Galilean Relativity in Newtonian Physics

The difficulty with Newton's view of absolute space comes from the Newtonian conception of force. If force is defined and measured solely by the power to accelerate a body, then obviously the effects of forces -- in short, the causal interactions within a system of bodies -- will be independent of the velocity of the system in which they are measured. So the existence of a set of equivalent "inertial frames" is imposed from the start by Newton's laws. Suppose that we determine for the bodies in a given frame of reference -- say, the rest frame of the fixed stars -- that all observable accelerations are proportional to forces impressed by bodies within the system, by equal and opposite actions and reactions among those bodies. Then we know that these physical interactions will be the same in any frame of reference that is in uniform rectilinear motion relative to the first one. Therefore no Newtonian experiment will be able to determine the velocity of a body, or system of bodies, relative to absolute space. In other words, there is no way to distinguish absolute space itself from any frame of reference that is in uniform motion relative to it. Newton thought that a coherent account of force and motion requires a background space consisting of "places" that "all keep given positions in relation to one another from infinity to infinity" (1726, p. 412). But the laws of motion enable us to determine an infinity of such spaces, all in uniform rectilinear motion relative to each other, and furnish no way of singling out any one as "immovable space."

Oddly enough, no one in the 17th century, or even before the late 19th century, expressed this equivalence of reference-frames more clearly than Newton himself. Newton explicitly derived it from the laws of motion as Corollary V:

> **Corollary V**:
> When bodies are enclosed in a given space, their motions in relation to one another are the same whether the space is at rest or whether it is moving uniformly straight forward without circular motion. (1726, p. 423.)

This is the first clear statement of the Galilean relativity principle. It implied that the dispute between the heliocentric and geocentric views of the universe was mistakenly framed: the proper question about "the system of the world" was not "which body is at rest in the center?" but "where is the center of gravity of the system, and which body is closest to it?" For in a system of orbiting bodies, only their common center of gravity will be unaccelerated, and by Corollary V, the motions of the bodies in the system will be the same, whether its center of gravity is at rest or in uniform rectilinear motion. The system is indeed approximately Keplerian, since the sun has by far the greatest mass and is therefore little disturbed from the center of gravity, which is therefore very close to the common focus of the approximately Keplerian ellipses in which the planets orbit the sun. But by Corollary V, the nearly-Keplerian structure of the system is completely independent of the system's state of motion in absolute space.

The Galilean relativity principle thus expressed the insight that different states of uniform motion, or different uniformly-moving frames of reference, determine only different points of view on the same physically objective quantities, namely force, mass, and acceleration. We can see this insight expressed more explicitly in Newton's understanding of inertia. For Leibniz (among others) , as we saw, moving force, the power of a body to change the motion of another, was determined by velocity. It was therefore seen as an active power, fundamentally different from the passive power of a resting body to resist any change of position. Newton, in contrast, understood the "force of inertia" as a Galilei-invariant quantity:

> [A] body exerts this force only during a change of its state, caused by another force impressed upon it, and the exercise of this force is, depending on viewpoint, both resistance and impetus: resistance in so far as the body, in order to maintain its state, strives against the impressed force, and impetus in so far as the same body, yielding only with difficulty to the force of a resisting obstacle, endeavors to change the state of that obstacle. Resistance is commonly attributed to resting bodies and impetus to moving bodies; but motion and rest, in the popular sense of the term, are distinguished from each other only by point of view, and bodies commonly regarded as being at rest are not always truly at rest. (1726, p. 404-05.)

Newton thus recognized the powers distinguished by Leibniz as the same thing seen from different points of view.

1.4 The Lingering Problem of Absolute Space

Newton understood the Galilean principle of relativity with a degree of depth and clarity that eluded most of his "relativist" contemporaries. It may seem bizarre, therefore, that the notion of inertial frame did not emerge until more than a century and a half after his death. He had identified a distinguished class of dynamically equivalent "relative spaces," in any of which true forces and masses, accelerations and rotations, would have the same objectively measured values. Yet these spaces, though empirically indistinguishable, were not equivalent in principle; evidently Newton conceived them as moving with various velocities in absolute space, though those velocities could not be known. Why should not he, or someone, have recognized the equivalence of these spaces immediately?

This is not the place for an adequate answer to this question, if indeed one is possible. For much of the 20th century, the accepted answer was that of Ernst Mach: Newton lived in an age "deficient in epistemological critique," and so was unable to draw the conclusion that these *empirically* indistinguishable spaces must be equivalent in *every* meaningful sense, so that no one of them deserves even in principle to be designated as "absolute space." Yet even those whom the 20th century credited with more sophisticated epistemological views, such as Leibniz, evidently had difficulties understanding force and inertia in a Galilei-invariant way, despite a philosophical commitment to relativity. Perhaps it suffices to say that to abandon the intuitive association of force or motion with velocity in space, and to accept an equivalence-class structure as the fundamental spatiotemporal framework, requires a level of abstraction that became possible only with the extraordinary development of mathematics, especially of a more abstract view of geometry, that took place in the 19th century. (See geometry: in the 19th century.) In the 17th century only Christiaan Huygens came close to expressing such a view; he held that not velocity, but velocity-difference, was the fundamental dynamical quantity. He therefore understood, for example, that the "absoluteness" of rotation had nothing to do with velocity relative to absolute space, but arose from the difference of velocity among different parts of a rotating body -- a difference which would, evidently, be the same irrespective of the velocity of the body as a whole in absolute space. But of this Huygens gave only the merest suggestion, in manuscripts that remained unpublished for two centuries. (See Stein 1977.) The concept of inertial frame therefore emerged only in the late 19th century, when, as we shall see, it did not seem to be of any great immediate importance.

1.5 19th-Century Analyses of the Law of Inertia

The development of this concept began with a renewed critical analysis of the notion of absolute space, for reasons not anticipated by Newton's contemporary critics. Its starting point was a critical questions about the law of inertia: relative to what is the motion of a free particle uniform and rectilinear? If the answer is "absolute space," then the law would appear to be something other than an empirical claim, for no one can observe the trajectory of a particle relative to absolute space. Two quite different answers to the question were offered in 1870, in the form of revised statements of the law of inertia. Carl Neumann proposed that when we state the law, we must suppose that there is a body somewhere in the universe -- the "body Alpha" -- with respect to which the motion of a free particle is rectilinear, and that there is a time-scale somewhere relative to which it is uniform (Neumann 1870). Ernst Mach (1883) claimed that the law of inertia, and Newton's laws generally, implicitly appeal to the fixed stars as a spatial reference-frame, and to the

rotation of the earth as a time-scale; at least, he held, such is the basis for any genuine empirical content that the laws have. The notion of absolute space, it followed, was only an unwarranted abstraction from the practice of measuring motions relative to the fixed stars.

Mach's proposal had the advantage of a clear empirical motivation; Neumann's "body Alpha" seemed no less mysterious than absolute space, and almost sounds comical to the modern reader. But Neumann's discussion of a time-scale was somewhat more fruitful. He noted that the law of inertia defines a time-scale: equal intervals of time are those in which a free particle travels equal distances. He also noted, however, that this definition is quite arbitrary. For, in the absence of a prior definition of equal times, any motion whatever can be stipulated to be uniform. It is no help to appeal to the requirement of freedom from external forces, since the free particles presumably are known to us only by their uniform motion. We have a genuine empirical claim only when we state of *at least two* free particles that their motions are *mutually* proportional; equal intervals of time can then be defined as those in which two free particles travel mutually proportional distances.

1.6. The Emergence of the Concept of Inertial Frame

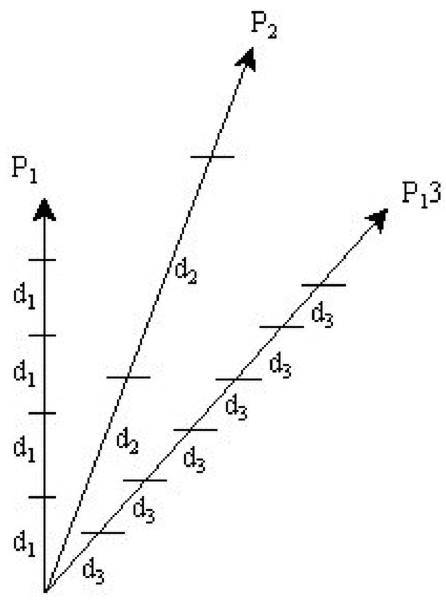
Neumann's definition of a time-scale directly inspired Ludwig Lange's conception of "inertial system," introduced in 1885 . An inertial coordinate system ought to be one in which free particles move in straight lines. But any trajectory may be stipulated to be rectilinear, and a coordinate system can always be constructed in which it is rectilinear. And so, as in the case of the time-scale, we cannot adequately define an inertial system by the motion of one particle. Indeed, for any two particles moving anyhow, a coordinate system may be found in which both their trajectories are rectilinear. So far the claim that either particle, or some third particle, is moving in a straight line may be said to be a matter of convention. We must define an inertial system as one in which at least three non-collinear free particles move in noncoplanar straight lines; then we can state the law of inertia as the claim that, relative to an inertial system so defined, the motion of any fourth particle, or arbitrarily many particles, will be rectilinear. The notions of inertial system and Neumann's time-scale, which Lange called an "inertial time-scale," may be combined as follows: relative to a coordinate system in which three free particles move in straight lines *and* travel mutually-proportional distances, the motion of any fourth free particle will be rectilinear and uniform. The questionable Newtonian concepts of absolute rotation and acceleration, Lange proposed, could now be replaced by the concepts of "inertial rotation" and "inertial acceleration," i.e. rotation and acceleration relative to an inertial system and inertial time-scale. See Figures 2 and 3.

Figure 2: Neumann's Time-Scale:
By Newton's first law, a particle not subject to forces travels equal distances in equal times. But which particles are free of forces? This might appear to be a matter of convention.

Either P_1 or P_2 can be arbitrarily stipulated to be at the origin of a system of coordinates, and to serve as the measure of equal times

But I can say of *two* particles with different velocities: in intervals of time in which one moves a given distance d_1, the other moves a proportional distance $d_2 = kd_1$ (where k is a constant; i.e., $d_1/d_2 = k$). Or I can compare a particle to a freely rotating planet: in intervals of time through which the planet rotates through equal angles, the particle moves equal distances.

Figure 3: Lange's Definition of 'inertial system' (1885):
An inertial system is a coordinate system with respect to which three free particles, projected from a single point and moving in non-coplanar directions, move in straight lines and travel mutually-proportional distances. The law of inertia then states that relative to any inertial system, any fourth free particle will move uniformly.



At about the same time, apparently unaware of the work of Mach, Neumann, and Lange, James Thomson expressed the content of the law of inertia, and the appropriate frame of reference and time-scale (“dial-traveller”), somewhat differently:

> For any set of bodies acted on each by any force, a REFERENCE FRAME and a REFERENCE DIAL-TRAVELLER are kinematically possible, such that relatively to them conjointly, the motion of the mass-centre of each body, undergoes change simultaneously with any infinitely short element of the dial-traveller progress, or with any element during which the force on the body does not alter in direction nor in magnitude, which change is proportional to the intensity of the force acting on that body, and to the simultaneous progress of the dial-traveller, and is made in the direction of the force. (Thomson 1884, p. 387)

More simply, an inertial reference-frame is one in which Newton’s second law is satisfied, so that every acceleration corresponds to an impressed force. Thomson did not reject the term “absolute rotation,” holding instead that it has to be understood as rotation relative to a reference frame that satisfies his definition. The definition does not express, as Lange’s does, the degree of arbitrariness involved in the construction of an inertial system by means of free particles. Moreover, like Lange’s, it leaves out a crucial condition for an inertial system as we understand it: all forces must belong to action-reaction pairs. Otherwise we could have, as on a rotating sphere, merely apparent (centrifugal) forces that are, by definition, proportional to mass and acceleration, and so the rotating sphere would satisfy Thomson’s definition. Therefore the definition needs to be completed by the stipulation that to every action there is an equal and opposite reaction. (This completion was actually proposed by R.F. Muirhead in 1887.)

But, so completed, Thomson’s definition has two advantages over Lange’s. First, by appealing to Newton’s second law instead of his first, it shows that we can apply the notion of inertial frame without having to consider the question whether there really are any free particles in nature. Second, it exhibits more clearly an essential point about the relation between the laws of motion and the inertial frames: that the laws assert the existence of at least one inertial frame. The original question, “relative to what frame of reference do the laws of motion hold?” is revealed to be wrongly posed. For the laws of motion essentially *determine* a class of reference frames, and (in principle) a procedure for constructing them. For the same reason, a skeptical question that is still commonly asked about the laws of motion -- why is it that the laws are true only relative to a certain choice of reference frame? -- is also wrongly posed. If Newton’s laws are true, then we can construct an inertial frame; their truth doesn’t depend on our ability to construct such a frame in advance.

2. Inertial Frames in the 20th Century: Special and General Relativity

2.1 Inertial Frames in Newtonian Spacetime

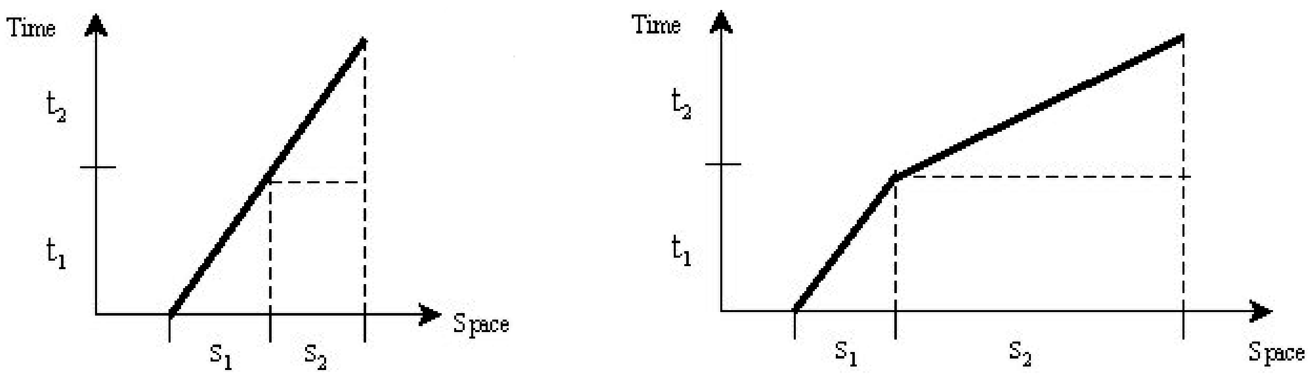
By the early years of the 20th century, this notion of inertial system seems to have been widely accepted, even if the specific works of Lange and Thomson were largely forgotten; in writing "On the electrodynamics of moving bodies" in 1905, Einstein took it to be obvious to his readers that classical mechanics does not require a single privileged frame of reference, but an equivalence-class of frames, all in uniform motion relative to each other, and any of which "the equations of mechanics hold good." Two inertial frames with coordinates (x, y, z, t) and ($x', y' z' t'$) are related by the *Galilean transformations*,

$$x' = x - vt$$
$$y' = y$$
$$z' = z$$
$$t' = t$$

(assuming that the x axis is defined to be the direction of their relative motion). These transformations clearly preserve the invariant quantities of Newtonian mechanics, i.e. acceleration, force, and mass (and therefore time, length, and simultaneity). As far as Newtonian mechanics was concerned, then, the problem of absolute motion was completely solved; all that remained was to express the equivalence of inertial frames in a simpler geometrical structure.

The lack of a privileged spatial frame, combined with the obvious existence of privileged states of motion -- paths defined as rectilinear in space and uniform with respect to time -- suggests that the geometrical situation ought to be regarded from a four-dimensional *spatiotemporal* point of view. The structure defined by the class of inertial frames can be captured in the statement that *spacetime is a four-dimensional affine space, whose straight lines* (geodesics) *are the trajectories of particles in uniform rectilinear motion*. See Figure 4.

Figure 4: Inertial Trajectories as Straight Lines of Spacetime

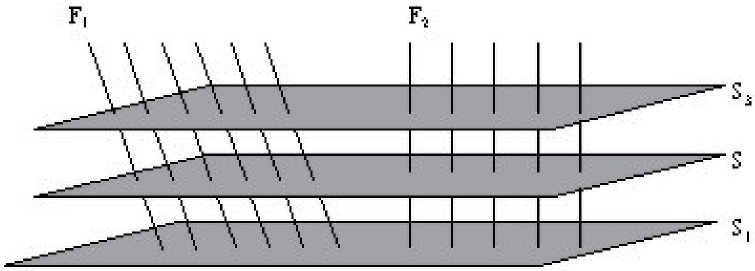


The uniformly moving particle will travel the same distance in the same intervals.

A particle that accelerates after t_1 will move a greater distance during t_2 and therefore its path *in spacetime* changes direction.

That is, spacetime is a structure whose automorphisms -- the Galilean transformations that relate one inertial frame to another -- are equivalent to affine transformations: they take straight lines into straight lines (i.e. an inertial motion in one inertial frame will be an inertial motion in any other inertial frame, and likewise for an accelerating or rotational motion), and parallel lines into parallel lines (i.e. uniformly-moving particles or observers who are relatively at rest in one frame will also be relatively at rest in another). (See Stein 1967, Ehlers 1973, and Friedman 1983 for further explanation.) An inertial frame can be characterized as a family of parallel straight lines "filling" spacetime, representing the possible trajectories of a family of free particles that are relatively at rest. See Figure 5:

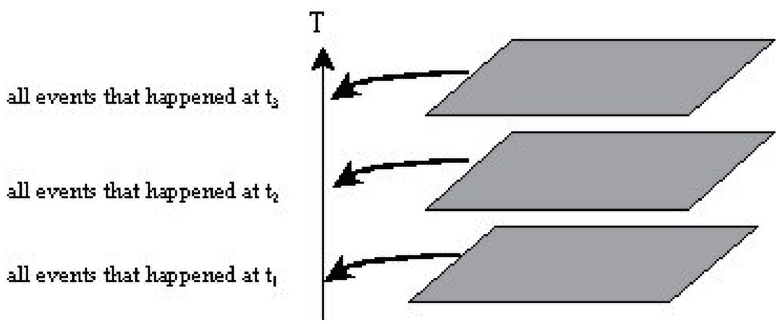
Figure 5:
Each of these families of straight lines, F_1 and F_2, represents the trajectories of a family of free particles that are relatively at rest, and therefore each defines an inertial frame. Relative to each other, the frames defined by F_1 and F_2 are in uniform motion.



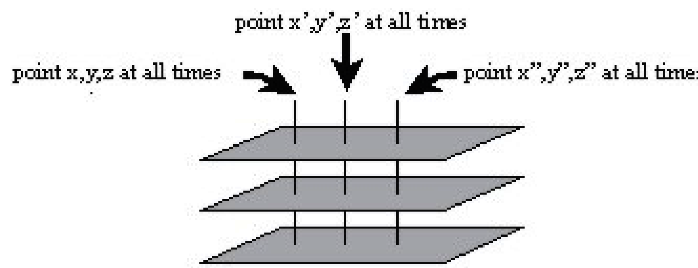
Each of the surfaces S is a "hypersurface of absolute simultaneity" representing all of space at a given moment; evidently (given the Galilean transformations) two inertial frames will agree on which events in spacetime are simultaneous.

From this we can see that the assertion that an inertial frame exists imposes a global structure on spacetime; it is equivalent to the assertion that spacetime is flat. As we can see from the Galilean transformations, distinct inertial frames will agree on time and simultaneity. Therefore, in the four-dimensional picture, the decomposition of spacetime into hypersurfaces of absolute simultaneity is independent of the choice of inertial frame. Another way of putting this is that Newtonian spacetime is endowed with a *projection* of spacetime onto time, i.e. a function that identifies spacetime points that have the same time-coordinate. Similarly, absolute space arises from a projection of spacetime onto space, i.e. a function that identifies spacetime points that have the same spatial coordinates. See Figure 6.

Figure 6:



The relation of simultaneity "decomposes" spacetime into 3-dimensional pieces, each representing "all of space at a given time," by projecting spacetime onto time, i.e., by identifying spacetime points that have the same time coordinates.



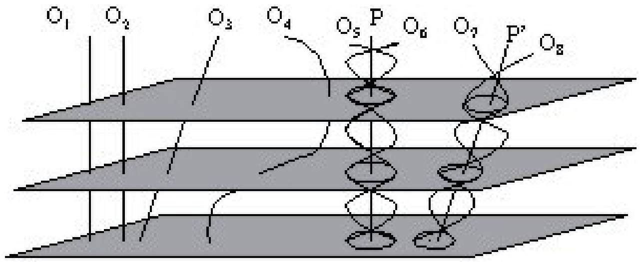
Similarly, one can think of the notion of "same place" as projecting spacetime onto space, i.e., by identifying spacetime points that have the same spatial coordinates; each of the trajectories thus singled out represents "a given place at all times."

But this latter projection is arbitrary: while it assumes that we can identify the same time at different spatial locations, Newtonian mechanics provides no physical way of identifying the same spatial point at different times. Thus the equivalence of inertial frames can be thought of as the arbitrariness of the projection of spacetime onto space, any such projection being, essentially, the arbitrary choice of some particular inertial frame as a rest-frame.

Figure 7: :

Here is a spacetime diagram of motions relative to the inertial frame in which O_1, O_2, and P are at rest. This can be seen as arising from the projection of each of their inertial trajectories onto a single point of space.

Here is the same situation viewed from an inertial frame in which O_3 and P' are at rest. Now O_1, O_2, and P are in uniform motion.



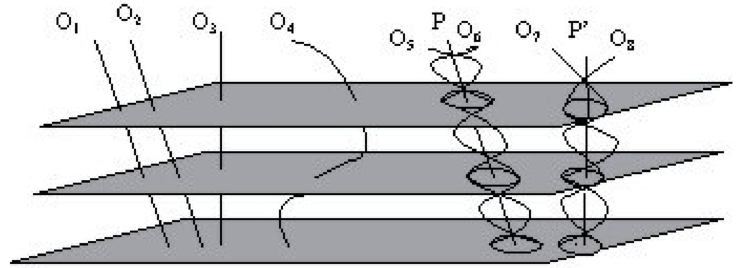
O_1 and O_2 are at rest

O_3 is in uniform motion

O_4 is accelerating any old way

O_5 and O_6 are revolving around their common centre of gravity P, which is at rest

O_7 and O_8 are revolving around their centre of gravity P′, which is in uniform motion.



O_3 is at rest

O_1 and O_2 are in uniform motion

O_4 is accelerating any old way

O_5 and O_6 are revolving around their common centre of gravity P, which is in uniform motion

O_7 and O_8 are revolving around their centre of gravity P′, which is at rest

2.2 The Conflict Between Galilean Relativity and Modern Electrodynamics

By the time that this representation of the Newtonian spacetime structure was developed, however, the Newtonian conception of inertial frame had been essentially overthrown. First, 19th-century electrodynamics raised again the question of a privileged frame of reference: the conception of light as an electromagnetic wave in the ether implied that the rest-frame of the ether itself should play a distinguished role in electrodynamical phenomena. On the one hand, physicists such as Maxwell and Lorentz were careful to point out that velocity relative to the ether was not equivalent to absolute velocity, and that the state of motion of the ether itself was necessarily unknown -- in other words, that this conception of light did not violate the classical principle of relativity. On the other hand, the existence of such a preferred frame made the equivalence of inertial frames correspondingly less interesting, even if it was true in principle. This is why the appearance of the idea of inertial frame in the 1880's, as I suggested earlier, was not of pressing physical interest to the majority of physicists, and seemed to be a mere philosophical sidelight. The attempts to measure the effects of motion relative to the ether commanded considerably more attention.

Second, the abandonment of the ether -- following the failure of attempts to measure velocity relative to the ether and, more generally, the apparent independence of all electrodynamical phenomena of motion relative to the ether -- did not vindicate the Newtonian inertial frame, but required a dramatically revised conception. Special relativity might be said to have applied the relativity principle of Newtonian mechanics to Maxwell's electrodynamics, by eliminating the privileged status of the rest-frame of the ether and admitting that the velocity of light is independent of the motion of the source. As Einstein expressed it, "the same laws of electrodynamics and optics will be valid for all frames of reference for which the equations of mechanics hold good." (1905, p. 38.) But as Einstein also pointed out, the invariance of the velocity of light and the principle of relativity, at least in its Galilean form, are incompatible. It simply makes no sense, according to Galilean relativity, that any velocity should appear to be the same in inertial frames that are in relative motion.

2.3 Special Relativity and Lorentz Invariance

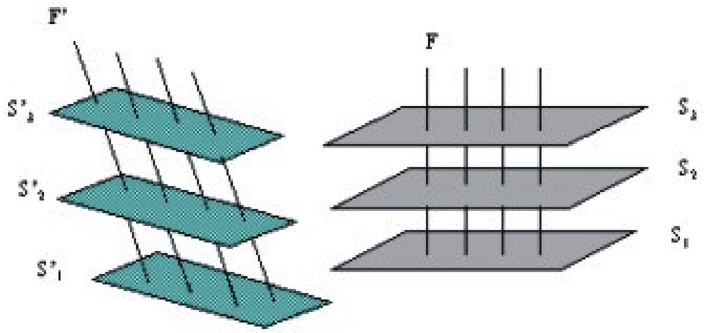
2.3. Special relativity and Lorentz invariance

Einstein solved this difficulty through his analysis of simultaneity: frames in relative motion can agree on the velocity of light only if they disagree on simultaneity; only the relativity of simultaneity makes possible the invariance of the velocity of light. This means that the transformations between inertial frames that preserve the velocity of light will not preserve simultaneity. These are the *Lorentz transformations*:

$$x' = \frac{x - vt}{\sqrt{1 - \frac{v^2}{c^2}}} \qquad y' = y \qquad z' = z \qquad t' = \frac{t - \frac{vx}{c^2}}{\sqrt{1 - \frac{v^2}{c^2}}}$$

Evidently these transformations do not preserve length and time, and so the invariant quantities of Newtonian mechanics, which presuppose invariant measures of length and time, must now depend on the choice of inertial frame. By the same token, the notions of force, mass, and acceleration can no longer be appealed to in the definition of an inertial frame. The definition must instead appeal to the invariant quantities of electrodynamics: an inertial frame is one in which light travels equal distances in equal times in arbitrary directions. What seems impossible, from the point of view of Galilean relativity, is that a frame that moves uniformly relative to such a frame should also satisfy the definition. But that, again, rests on the assumption that two inertial frames will have a common measure of simultaneity. If, as Einstein asserts, the only reasonable definition of simultaneity is one provided by light signals, then there is no determination of simultaneity that will give the same results in different inertial frames. The spacetime structure that is implied by special relativity is thus an affine space, like Newtonian spacetime, but it is not objectively divided into hypersurfaces of absolute simultaneity; the sets of simultaneous events for any inertial frame are the hyperplanes orthogonal to the trajectories that determine that frame. In other words, the choice between two inertial frames determines a choice between two distinct divisions of spacetime into space and time. See Figure 8:

Figure 8:
The inertial frames F and F′ are in relative motion, and therefore, as the Lorentz transformations indicate, they disagree on simultaneity. F and F′ thus determine distinct decompositions of spacetime into instantaneous spaces, S and S′, respectively



2.4 Simultaneity and Reference-Frames

The details of Einstein's argument and the structure of Minkowski spacetime can be found elsewhere (see, e.g., Einstein 1951 and Geroch 1978). Here only one more point is worth making. It could be argued that Einstein's and Lorentz's view are completely equivalent. That is, we could assume that there is indeed a privileged frame of reference, and that the apparent invariance of the velocity of light is explained by the effects on bodies of their motion through the ether (the Lorentz contraction and time dilation). This purported distinction between empirically indistinguishable frames has often been criticized on straightforward methodological grounds, but it could be (and surely has been) argued that it is more intuitively plausible than the relativity of simultaneity. After all, knowing that (as Einstein showed) the Lorentz contraction can be derived from the invariance of the velocity of light does not, by itself, entitle us to say which of the two is the more convincing starting-point.

This is why it is so important that Einstein's 1905 paper begins with a critical analysis of the entire notion of a frame of reference. It is tacitly assumed by Lorentz's theory, and classical electrodynamics generally, that we have a reference-frame in which we can measure the velocity of light. But how is such a reference-frame determined? The distances between points in space can only be determined if it is possible to determine which events are simultaneous. In practice this is always done by light-signalling, if only in the informal sense that we identify simultaneous events when we see them at the same time. But if the spatial frame of reference is determined by light-signals, and is then to be used to measure the speed of light, we would appear to be going in a circle; the underlying assumption must be that, while light-signalling is useful and practical, it is not essential to the definition of simultaneity, and that there is a fact of the matter about which events are simultaneous that is independent of this method of signalling. This assumption was actually made explicit by James Thomson. He recognized -- alone, apparently, before Einstein -- that the measurement of distance involves

> the difficulty as to imperfection of our means of ascertaining or specifying, or clearly idealizing, simultaneity at distant places. For this we do commonly use signals by sound, by light, by electricity, by connecting wires or bars, and by various other means. The time required in the transmission of the signal involves an imperfection in human powers of ascertaining simultaneity of occurrences at distant places. It seems, however, probably not to involve any difficulty of idealizing or imagining the existence of simultaneity. Probably it may not be felt to involve any difficulty comparable to that of attempting to form a distinct notion of identity of place at successive times in unmarked space. (1884, p. 380).

In other words, Thomson assumed that it was not a difficulty in principle, like the difficulty of determining rest in absolute space. But Einstein showed that it was precisely the same kind of difficulty, and that determinations of simultaneity involve reference to an arbitrary choice of reference-frame, just as much as determinations of velocity. Einstein's conclusion is, of course, entirely contingent on the empirical facts of electrodynamics; it could have been avoided if there were in nature a useful signal of some kind whose transmission would provide a criterion of absolute simultaneity, so that the same events would be determined to be simultaneous in all inertial frames. Or, experiments might have been able to reveal the dependence of the velocity of light on the state of motion of the source. Then synchronization by light-signals could still have been regarded as a mere practical substitute for a notion of absolute simultaneity that stood on independent grounds, empirically as well as conceptually. But as Einstein saw, because of the apparent independence of the velocity of light of the motion of the source, even "idealizing or imagining the existence of simultaneity" involves light-signaling more essentially than anyone could have realized. Unless some other criterion of simultaneity is provided, therefore, the establishment of a spatial frame of reference involves light-signaling in an essential way. In the absence of such a criterion the speed of light cannot be, as Lorentz supposed, empirically measured against the background of an inertial frame; in that case the only empirically sound definition of an inertial frame is the one that appeals to the speed of light.

2.5 From Special Relativity and Lorentz Invariance to General Relativity and General Covariance

It may seem surprising that, after this insightful analysis of the concept of inertial frame and its role in electrodynamics, Einstein should have turned almost immediately to call that concept into question. But he had a compelling combination of physical and philosophical motives to do so. On the physical side, he realized (along with many others) that special relativity would require some fundamental revision of the Newtonian theory of gravity. On the philosophical side, he became convinced, largely by his reading of Mach (1883), that the central role of inertial frames was an "epistemological defect" that special relativity shared with Newtonian mechanics. (Einstein 1916, pp. 112-113.) Only relative motions are observable, yet both of these theories purport to identify a privileged state of motion and use it to explain observable effects (such as centrifugal forces). Coordinate systems are not observable, yet both of these theories assign a fundamental physical role to certain kinds of coordinate system, namely, the inertial systems. In either theory, inertial coordinates are distinguished from all others, and the laws of physics are said to hold only relative to inertial coordinate systems. In an epistemologically sophisticated theory, both of these problems would be solved at once: the new theory would only refer to what is observable, which is relative motion; it would admit arbitrary coordinate systems, instead of confining itself to a special class of system. Why, after all, should any genuine physical phenomenon depend on the choice of coordinate system?

Another way of putting the same point is to say that, in Newtonian mechanics and special relativity, rotation is "absolute" because the transformations between inertial frames (Galilean or Lorentzian) preserve rotational states. Thus the "absoluteness" of rotation arises precisely from singling out one type of frame, by one type of transformation, instead of allowing arbitrary transformations and arbitrary frames. Einstein held that this epistemological insight had a natural mathematical representation in the principle of *general covariance*, or the principle that the laws of nature are to be invariant under *arbitrary* coordinate transformations. More precisely, what this means is that coordinate transformations are no longer required (as in the affine spaces of Newtonian mechanics and special relativity) to take straight lines to straight lines, but only to preserve the smoothness of curves (i.e. their differentiability). The general theory of relativity was intended to be a generally covariant account of spacetime, and its general covariance was intended to express the general relativity of motion. And the theory came into being because Einstein perceived a deep connection between this project and that of finding a relativistic theory of gravitation.

2.6 The Equivalence of Inertia and Gravity

The philosophical motivations and implications of Einstein's view are dealt with elsewhere. (See, for example, the entries on Einstein's philosophy of science; the hole argument; and early philosophical interpretations of general relativity.) We will consider here only the bearing of general relativity on the notion of an inertial frame. It is questionable whether Einstein succeeded in

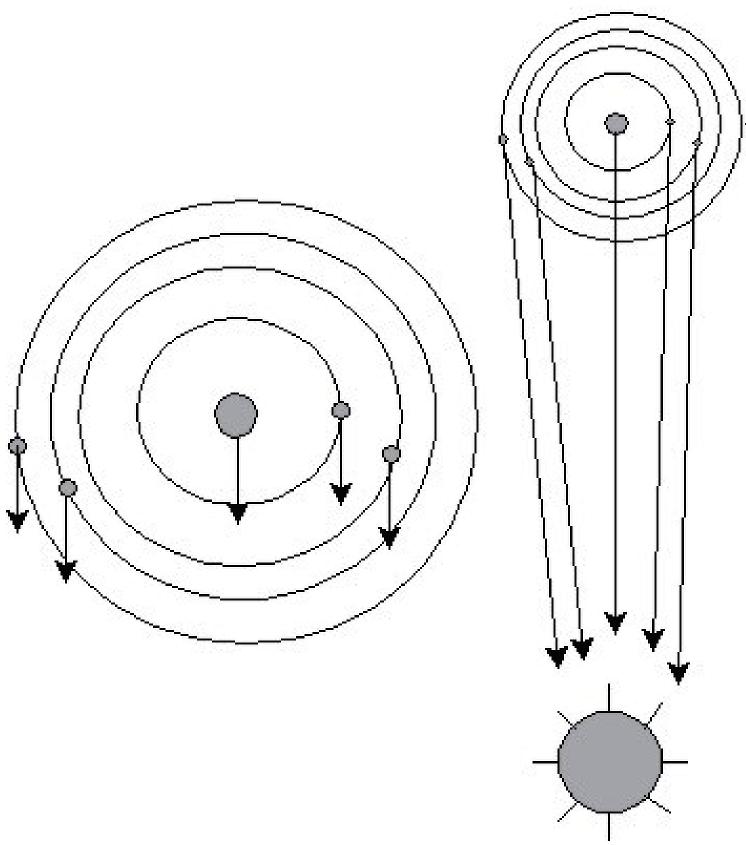
establishing the general relativity of motion, but it is clear that general relativity undermines the concept of inertial frame in important respects. This arises from the *equivalence principle*: that inertial mass -- the quantity that enters into Newton's second law, and that is a measure of a body's resistance to acceleration -- is equivalent to gravitational mass, the quantity that enters into Newton's law of universal gravitation. A more empirical way of expressing it is that all bodies fall with the same acceleration in the same gravitational field, or, the trajectory of a body in a given gravitational field will be independent of its mass and composition. This is the principle that Newton tested by constructing pendulums with wooden boxes as their bobs, which he would fill with different materials in order to see whether those differences made a difference to the speed of falling; they didn't. Eötvös made more precise tests in the late 19th century, and established the principle to much greater accuracy; these are the results on which Einstein would have relied. Newton also tested the principle for bodies whose masses differ greatly, by observing that Jupiter and its four moons all received precisely the same acceleration from the sun's gravitational field.

The equivalence principle suggests, however, that a freely-falling frame of reference is physically indistinguishable from an inertial frame. Newton had already noticed this, and indeed he stated it, more or less, in Corollary VI to the laws of motion:

> If bodies are moving in any way whatsoever with respect to one another and are urged by equal accelerative forces along parallel lines, they will all continue to move with respect to one another in the same way as they would if they were not acted on by those forces. (1726, p. 423.)

For example, he was able to treat the system of Jupiter and its moons as if it were (nearly) at rest or moving uniformly in a straight line, because the attractive force of the sun acts (almost) equally on every part of the system. See Figure 9:

Figure 9: Newton's Corollary VI
What seem, within a given system, like equal and parallel accelerations may be, on a larger scale, unequal and converging on some distant massive object; e.g., the system of Jupiter and its moons is falling toward the sun, but "locally" the accelerations are very nearly equal and parallel, and may therefore be neglected.



He even applied this reasoning to the entire solar system, in order to justify treating it as an isolated system: if there were any outside force acting on it, it must have been acting more or less equally and in parallel directions on all parts of the system.

> It may be alleged that the sun and planets are impelled by some other force equally and in the direction of parallel lines;

> but by such a force (by Cor. VI of the Laws of Motion) no change would happen in the situation of the planets to one another, nor any sensible effect follow; but our business is with the causes of sensible effects. Let us, therefore, neglect every such force as imaginary and precarious, and of no use in the phenomena of the heavens....(1729, volume 2 p. 558)

Now, it is a familiar fact that in an orbiting spacecraft, bodies behave as if no forces were acting on any of them (as if they were “weightless”), because the attraction of the earth acts equally on all of them. But these phenomena are not, by themselves, evidence that *no* phenomena are capable of distinguishing an inertial frame from a falling frame. Einstein was willing to generalize the equivalence principle, and to conclude that the classical idea of a distinguished class of frames of reference has no physical basis. Any frame that we might regard as inertial might be, for all we can tell by experiment, in free fall. By the same token, any frame that is uniformly accelerating is indistinguishable from one that is at rest in a uniform gravitational field. Suppose that you are in a box at rest on the earth; you and everything in the box, by the equivalence principle, will be accelerated downward with the acceleration g (= 9.8 meters/second/second). Now suppose that the box itself is in empty, gravity-free space, but accelerating upward (i.e. in the direction of its roof) with the acceleration $-g$. Obviously, because of their inertia, bodies in the box, including your own, will exert the same force -- have the same “weight” -- on the floor as if the box were at rest and sitting on the earth.

2.7 The Equivalence Principle and General Covariance

To get a clearer idea of the physical significance of the equivalence principle, and its connection with general covariance, consider the Newtonian procedure for analyzing motion in the solar system, here sketched very roughly:

1. Determine the accelerations of all the planets relative to the fixed stars.
2. Using the laws of motion, their corollaries, and all the propositions proved from these in Book I of Principia, derive from the accelerations the forces needed to produce them; in particular, derive from the orbits the centers of those orbits, and the masses of the bodies needed to produce those forces. This crucially involves the law of action and reaction, for otherwise it would be impossible to break down the total acceleration of any planet into the components contributed by particular other planets; the earth’s acceleration, for example, is the sum of its accelerations toward all the other planets, and each individual acceleration is part of an action-reaction pair involving some other planet.
3. When we understand the mutual interactions among the planets, we are in a position to estimate their relative masses. In Newton’s case, this was necessarily restricted to the planets with satellites, because only in those cases could he compare the accelerations they determine at given distances and so deduce the differences in mass. By this reasoning he estimated the ratios of the Sun’s mass to those of Jupiter (1067 to 1), Saturn (3021 to 1), and the earth, and was able to calculate that the center of mass of the entire solar system would never be more than one solar diameter from the center of the Sun.
4. Having found the center of mass, we have in principle determined an inertial frame: by Corollary IV to the laws of motion, the center of mass will be at rest or moving uniformly in a straight line. That is, the mutual actions of the bodies in the system will not change the state of motion of the center of mass. And having determined an inertial frame, we are in a position to say that the accelerations relative to the center of mass frame are the true accelerations.

One might think that the problem of relativity arises right from the start: the reliance on the fixed stars already seems to introduce an arbitrary assumption that threatens to vitiate Newton’s procedure as an account of the true motions. But the framework of the fixed stars, initially just taken for granted, turns out to be justified in the course of the analysis. If it turns out that all the accelerations relative to the fixed stars can be analyzed into action-reaction pairs involving bodies within the system, leaving no “leftover” accelerations that need to be traced to some yet-unknown influence, then we can conclude that the stars are a suitable (sufficiently inertial) frame of reference after all. (By the later 19th century, observations became sufficiently precise to reveal that there is in fact a leftover acceleration, namely the famous extra precession of Mercury. But that could not affect Newton’s analysis in 1687.) In contrast, had we chosen the earth as a frame of reference, we would find that there are accelerations relative to this frame -- e.g. Coriolis and centrifugal accelerations -- that don’t satisfy the law of action and reaction.

2.8 The Extension of the Relativity Principle

The relativistic aspect of this situation arises from the equivalence principle. Newton’s Corollary VI said that the inertial frame we construct by this procedure is effectively indistinguishable from one in which all the bodies are undergoing equal and parallel accelerations caused by some force that acts equally on all of them; the equivalence principle asserts that gravity is such a force. In following the Newtonian procedure for constructing an inertial frame, we have constructed a frame which might be, for all we can determine empirically, falling in the gravitational field of some other system. This means that the accelerations relative to this frame

cannot be known to be the “true accelerations”; they may be accelerations relative to a freely-falling trajectory just in case the center of mass is itself freely falling, in which case they have to be added to the gravitational acceleration of the center of mass before we can arrive at the true accelerations. But the acceleration of the center of mass may have to be added to some larger acceleration--and so on. This means that we can’t know the true strength of the gravitational field by observing the motions in this frame. The only hope of doing so would be to include all the mass in the universe in one dynamical system; if we knew the center of mass of the entire universe, we could rule out the possibility that something else is exerting an accelerative force, since by hypothesis there would be nothing else.

We can see the significance of this more clearly by looking at the equations of motion (in a very simplified form). Newton’s equation of motion for a particle subject to no force asserts that it moves uniformly, with zero acceleration. Obviously, in a gravitational field, the particle’s acceleration will depend on the field. In effect, we are accounting for the trajectory of the falling particle by “decomposing” it into two parts, the part determined by its natural tendency to move uniformly in a straight line, and the part contributed by the gravitational field. But by the analysis of the equivalence principle, determining the inertial part--and therefore determining the gravitational part--depends on our assumption that the center of mass frame is inertial rather than freely falling. And this assumption is arbitrary; that is, it amounts to an arbitrary choice of the coordinate system in which we define the equation of inertial motion. This implies that the gravitational field depends on the coordinate system in precisely the same way.

The principle of general covariance, then, acquires its physical significance in conjunction with the equivalence principle. By itself, it says that the geometrical structures of spacetime don’t depend on the coordinates in which we express them, or on the set of points that we may think comprises spacetime. This is an important principle, but it doesn’t recommend general relativity over other theories, since special relativity and Newtonian mechanics also involve spacetime structures that can be defined in a generally-covariant way, through the same kinds of coordinate-independent mathematical objects that we use in general relativity. Combined with the equivalence principle, however, it implies that a central Newtonian idea--that gravity is a force causing deviations from uniform rectilinear motion-- is based on an arbitrary choice of coordinates. For a trajectory that satisfies all empirical criteria for being inertial in a particular frame of reference--e.g. the trajectory of the center of mass in our example--may be freely falling relative to some other trajectory that satisfies the same criteria. By contrast, a freely-falling trajectory is a freely falling trajectory in any coordinate system; it is only the decomposition of it into its inertial and gravitational parts that will be different in different coordinate systems.

2.9 From Inertial Frames to Curved Spacetime

General covariance is thus not an argument against privileged states of motion, as Einstein had hoped it would be. It is an argument that the privileged states of motion should not be mere artifacts of our choice of coordinates, i.e. that they should be coordinate-independent. Precisely what this means depends, then, on what physical means we have at our disposal to identify states of motion other than by simply setting down coordinates. Combined with the equivalence principle, it is an argument for regarding gravitational free-fall as the privileged state of motion, rather than as a forced deviation from the privileged state of motion. And in this way it provides an argument for spacetime curvature. As we saw, in Newtonian and Minkowski spacetime the inertial trajectories are, by definition, the straight lines or geodesics of spacetime. And the flatness of spacetime consists in the fact that these geodesics behave like straight lines in a flat space or surface: parallel geodesics remain parallel, and non-parallel geodesics do not accelerate relative to one another. (In any inertial frame, the motion of any other inertial frame appears uniform.) By the equivalence principle, however, free-fall trajectories satisfy all empirical criteria for being inertial trajectories, and so the distinction between the two types of trajectory depends on the mere choice of coordinates. General covariance suggests, then, that the free-fall trajectories ought to be identified as the inertial trajectories -- and therefore, as the geodesics of spacetime. But if free-fall trajectories are the geodesics of spacetime, then spacetime is curved. For the free-fall trajectories exhibit relative accelerations, and the relative acceleration of geodesics is a defining characteristic of curved geometry. The curvature of the earth’s surface, for example, is revealed in the fact that geodesics that begin in parallel directions can begin to approach one another -- for example, two lines of longitude can both be perpendicular to the equator, but converge on one another as they approach the poles. And since the relative accelerations of falling bodies depend on the distribution of mass, as we already knew from Newton’s theory, we now conclude not only that spacetime is curved, but that its curvature is determined by the distribution of mass. (For further explanation see Geroch 1978.)

The curvature of spacetime, finally, determines the status of inertial frames in general relativity. The statement that all reference-frames, rather than just inertial frames, are equivalent is a misleading way of describing the situation; rather, the variable curvature of spacetime makes the imposition of a global inertial frame impossible. So the status of the latter is like the status of a plane rectangular coordinate system on the surface of the earth. Over a sufficiently small area, the coordinate plane may be a good approximation to the surface, but over increasingly large areas it diverges increasingly from the contours of the earth. And if two such coordinate systems,

with their origins at different points on the earth, are extended until they meet, they will be seen to be “disoriented” relative to one another. In contrast, a flat plane can be so coordinatized, and coordinate systems originating at different points can be smoothly combined into one system. Similarly, in the affine spaces of Newtonian and special-relativistic physics, any inertial coordinate system can be extended over the whole of spacetime. And in any system so extended, the trajectory of every other inertial observer will be a uniform rectilinear motion. But if spacetime is variably curved, according to the distribution of mass and energy, local inertial systems will be “disoriented” relative to one another; indeed, the degree of this “disorientation” is one of the measures of curvature. And an inertially-moving -- i.e. freely falling -- particle will in that case be accelerating in the local inertial system of another freely-falling particle. Thus there are inertial trajectories, but no extended inertial systems. See Figures 10 - 13:

Figure 10:
This Cartesian coordinate system can evidently be simply “set down” over the plane below. Any coordinate system defined at any point of the plane can be smoothly extended over the entire plane.

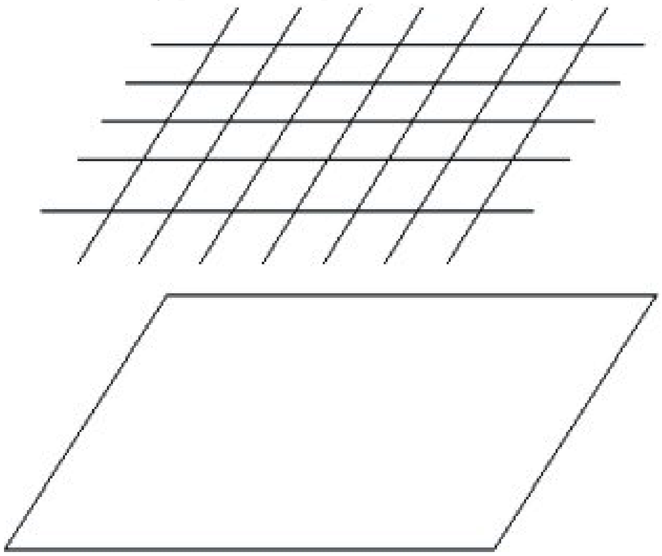


Figure 11: “Magnified” View of Flat “Local” Coordinate Systems on a Curved Surface

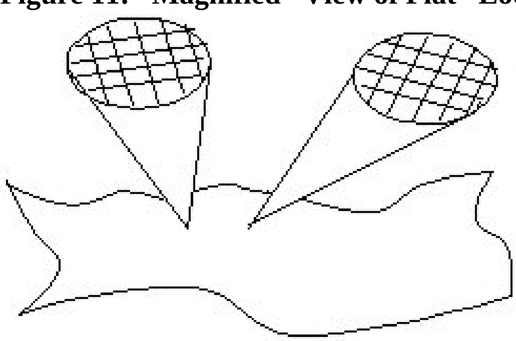

This arbitrary curved surface won’t allow for the global laying down of a coordinate system, but must be coordinatized in small overlapping pieces, which generally won’t be parallel to one another.

Figure 12:
In a flat spacetime, the rest-frame of any inertial observer an be “extended” over all of spacetime in such a way that, in this global inertial frame, the trajectory of every other inertial observer will be an inertial trajectory.

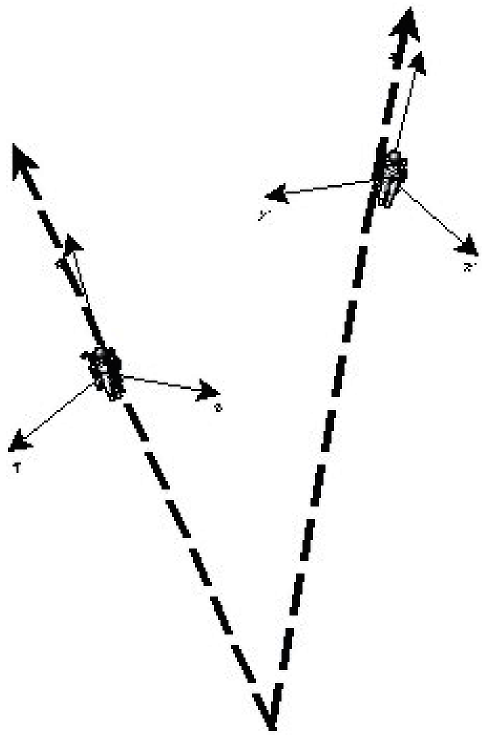

Figure 13:
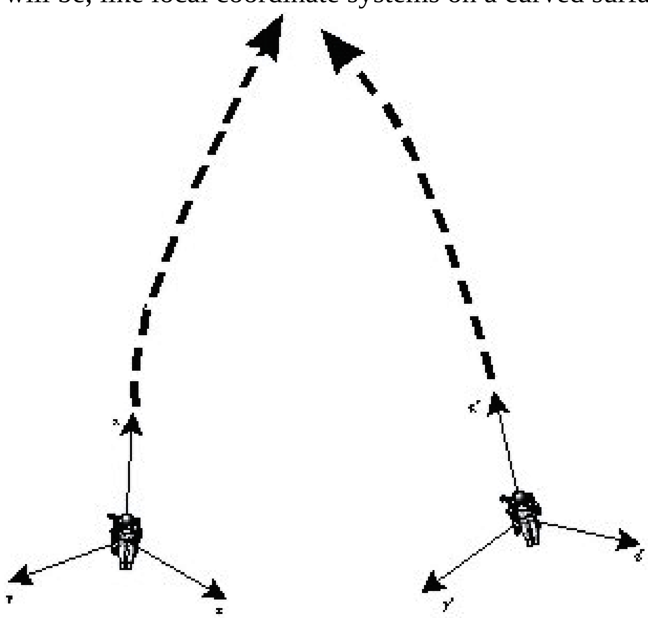
In a curved spacetime, inertial trajectories will be relatively accelerated; indeed the relative acceleration of geodesics is a measure of curvature. Therefore the local inertial frame of any freely-falling observer cannot be extended into a global frame in which all other inertial observers are moving uniformly. The inertial frames of different freely-falling observers will be, like local coordinate systems on a curved surface, “disoriented” relative to one another.



One could try to express this idea with Einstein’s remark about the need to “free oneself from the idea that coordinates must have an immediate metrical meaning.” (Einstein 1949, p. 67.)But even this might be misleading. Einstein evidently was thinking that, in general relativity, coordinates, and coordinate transformations, no longer represent the possible displacements of rigid bodies or the transport of ideal clocks. The insight underlying this is that the notion of rigid displacement -- therefore of rigid coordinate system, and inertial frame -- imposes *a priori* a degree of uniformity, or symmetry, on spacetime; the displacement of bodies without change of dimension, and the transport of an ideal clock without distortion of time-intervals, requires a homogeneous space. And so rigid displacement cannot be a basic principle in a theory in which spacetime curvature varies according to the distribution of mass and energy. The possibility of a rigid displacement, and therefore the existence of an inertial frame, can only arise *a posteriori*, as the result of a peculiar distribution of mass-energy (for example, in a universe empty of mass and energy, or with a highly symmetrical distribution). The serious defect in the notion of inertial frame is not that it makes an arbitrary distinction among coordinate systems --

for the distinction is quite as genuine as the distinction between flat and curved spacetime -- but that it extends indefinitely over spacetime a structure that, in our universe, only corresponds approximately to very small regions.

Nineteenth Century Geometry

In the nineteenth century, geometry, like most academic disciplines, went through a period of growth that was near cataclysmic in proportion. During the course of this century, the content of geometry and its internal diversity increased almost beyond recognition; the axiomatic method, highly touted since antiquity by the admirers of geometry, attained true logical sufficiency, and the ground was laid for replacing the standard geometry of Euclid by Riemann's more pliable system in the description of physical phenomena. Modern philosophers of all tendencies --- Descartes and Hobbes, Spinoza and Locke, Hume and Kant --- had regarded Euclidean geometry as a paradigm of epistemic certainty. The downgrading of Euclidean geometry to a subspecies of the vast family of mathematical theories of space shattered philosophical illusions and prompted important changes in our understanding of human knowledge. After these nineteenth-century developments, those who thirst for an absolute knowledge of right and wrong can no longer propose Euclidean geometry as the one instance in which a like goal has proved attainable. The present article reviews the aspects of nineteenth century geometry that are of major interest for philosophy and hints, in passing, at their philosophical significance.

---

1. Lobachevskian geometry

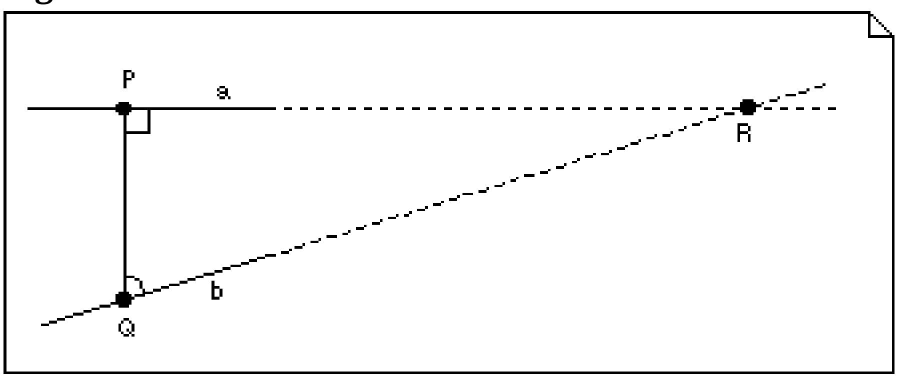
Euclid (fl. 300 b.c.) placed at the head of his *Elements* a series of 'definitions' (e.g., "A point is that which has no part") and 'common notions' (e.g., "If equals be added to equals, the sums are equal"), and five 'requests'. Supposedly these items conveyed all of the information needed for inferring the theorems and solving the problems of geometry, but as a matter of fact they do not. However, the requests

(*aitemata*)---usually called ‘postulates’ in English---must at any rate be granted or Euclid’s proofs will not go through. Some of them are plainly practical:

> 1. To draw a straight line from any point to any point.
> ...
> 3. To draw a circle with any center and any radius.

However, the fifth one sounds more like a statement of fact. Still, it can readily be paraphrased as a recipe for constructing triangles: Given any segment PQ, draw a straight line a through P and a straight line b through Q, so that a and b lie on the same plane; verify that the angles that a and b make with PQ on one of the two sides of PQ add up to less than two right angles; if this condition is satisfied, it should be granted that a and b meet at a point R on that same side of PQ, thus forming the triangle PQR. (See Figure 1.) This request is known as "Euclid’s Postulate".

Figure 1



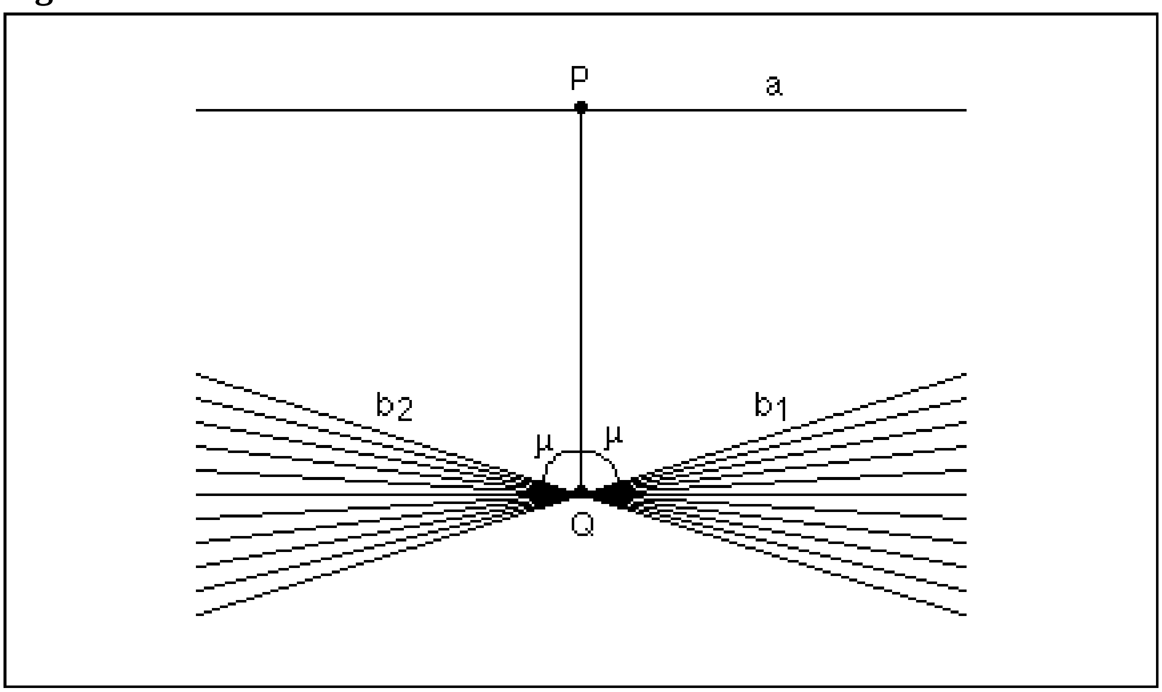
In the darker ages that followed, Euclid’s sense of mathematical freedom was lost and philosophers and mathematicians expected geometry to rest on self-evident grounds. Now, if a is perpendicular and b is almost perpendicular to PQ, a and b approach each other very slowly on one side of PQ and it is not self-evident that they must eventually meet somewhere on that side. After all, the hyperbole indefinitely approaches its asymptotes and yet, demonstrably, never meets them. Through the centuries, several authors demanded---and attempted---a proof of Euclid’s Postulate. John Wallis (b. 1616, d. 1703) derived it from the assumption that there are polygons of different sizes that have the same shape. But then this assumption needs proof in turn. Girolamo Saccheri (b. 1667, d. 1733) tried *reductio*. He inferred a long series of propositions from the negation of Euclid’s Postulate, until he reached one which he pronounced "repugnant to the nature of the straight line". But Saccheri’s understanding of this "nature" was nourished by Euclidean geometry and his conclusion begged the question.

In the 1820’s, Nikolai I. Lobachevsky (b. 1793, d. 1856) and Janos Bolyai (b. 1802, d. 1860) independently tackled this question in a radically new way. Lobachevsky built on the negation of Euclid’s Postulate an alternative system of geometry, which he dubbed "imaginary" and checked---inconclusively---for validity at the astronomical scale. Bolyai excised the postulate from Euclid’s system; the remaining rump is the "absolute geometry", which can be further specified by adding to it either Euclid’s Postulate or its negation. From the 1790’s Carl Friedrich Gauss (b. 1777, d. 1855) had been

working on the subject in the same direction, but he refrained from publishing for fear of scandal. Since Lobachevsky was the first to publish, the system of geometry based on the said "absolute geometry" plus the negation of Euclid's Postulate is properly called *Lobachevskian geometry*.

The construction introduced above to explain Euclid's Postulate can also be used for elucidating its negation. Draw the straight line a through point P at right angles with the segment PQ. If Euclid's Postulate is denied, there are countless straight lines through Q, coplanar with a, that make acute angles with PQ but never meet a. Consider the set of real numbers which are the magnitudes of these acute angles. Let the greatest lower bound of this set be μ. Evidently, μ > 0. There are exactly two straight lines through Q, coplanar with a, that make an angle of size μ with PQ. (See Figure 2.) Call them b_1 and b_2. Neither b_1 nor b_2 meets a, but a meets every line through Q that is coplanar with a and makes with PQ an angle less than μ. Gauss, Lobachevsky and Bolyai---unbeknownst to each other---coincided in calling b_1 and b_2 *the parallels* to a through Q. μ is called the angle of parallellism for segment PQ. Its size depends on the length of PQ, and decreases as the latter increases.

Figure 2



Suppose that the angle of parallellism for PQ is one half a right angle. In this case, b_1 and b_2 make a right angle at Q and we thus have two mutually perpendicular straight lines on the same plane as a, which fail to meet a.

Lobachevsky's geometry abounds in surprising theorems (many of which had already been found by Saccheri). Here are a few: The three interior angles of a triangle add up to *less* than two right angles. The difference or "defect" is proportional to the triangle's area. Hence, in Lobachevskian geometry, similar triangles are congruent. Moreover, if a triangle is divided into smaller triangles, the defect of the whole equals the sum of the defects of the parts. Since the defect cannot be greater than two right angles, the

area of triangles has a finite maximum. If a quadrilateral, by construction, has three right angles, the fourth angle is necessarily acute. Thus, in Lobachevskian geometry there are no rectangles.

There is a simple formal correspondence between the equations of Lobachevskian trigonometry and those of standard spherical trigonometry. Based on it, Lobachevsky argued that any contradiction arising in his geometry would inevitably be matched by a contradiction in Euclidean geometry. This is apparently the earliest instance of a proof of relative consistency, by which a theory is shown to be at least as consistent as another one (whose consistency is taken for granted).

Lobachevskian geometry received little attention before the late 1860’s. When philosophers finally took notice of it, their opinions were divided. Some regarded it as a formal exercise in logical deduction, with no physical or philosophical significance, which employed ordinary words---such as ‘straight’ and ‘plane’---with a covertly changed meaning. Others welcomed it as sufficient proof that, contrary to the influential thesis of Kant, Euclidean geometry does not convey any prerequisites of human experience and that the geometrical structure of physical space is open to experimental inquiry. Still others agreed that Non-Euclidean geometries were legitimate alternatives, but pointed out that the design and interpretation of physical experiments generally presupposes a definite geometry and that this role has been preempted by Euclid’s system.

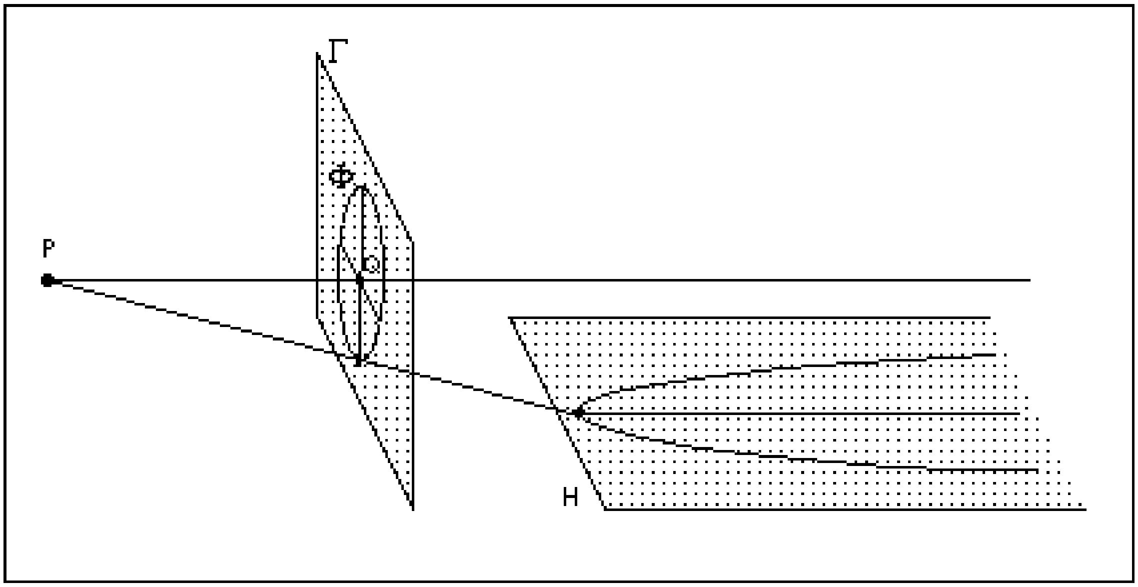
No matter what philosophers might say, for mathematicians Lobachevskian geometry would probably have been no more than an odd curiosity, if a niche had not been found for it within both projective and differential geometry, the two main currents of nineteenth-century geometrical research (§§ 2 and 5).

2. Projective geometry

Today projective geometry does not play a big role in mathematics, but in the late nineteenth century it came to be synonymous with modern geometry. Projective methods had been employed by Desargues (b. 1591, d. 1661) and Pascal (b. 1623, d. 1662), but were later eclipsed by Descartes’s method of coordinates. They prospered, however, after Jean-Victor Poncelet (b. 1788, d. 1867) showed that the projective properties of figures furnished grounds of proof that were at least as powerful as, and certainly more geometric than the Cartesian procedure of setting up and solving equations between numbers representing points.

Projective properties are those preserved by projections. Take, for example, two planes Γ and H and a point P outside them. Let Φ be any figure on Γ. Draw straight lines from P through each point of Φ. The figure formed by the points where these lines meet H is the projection of Φ on H from P. Generally this figure will differ from Φ in size and shape. But the projection of any number of straight lines on Γ meeting each other at certain points generally consists of an equal number of straight lines on H meeting respectively at the projection of those points. What happens, however, if the straight line joining P with a some point Q of Γ never meets H, because PQ happens to lie on a plane parallel to H? (See Figure 3.)

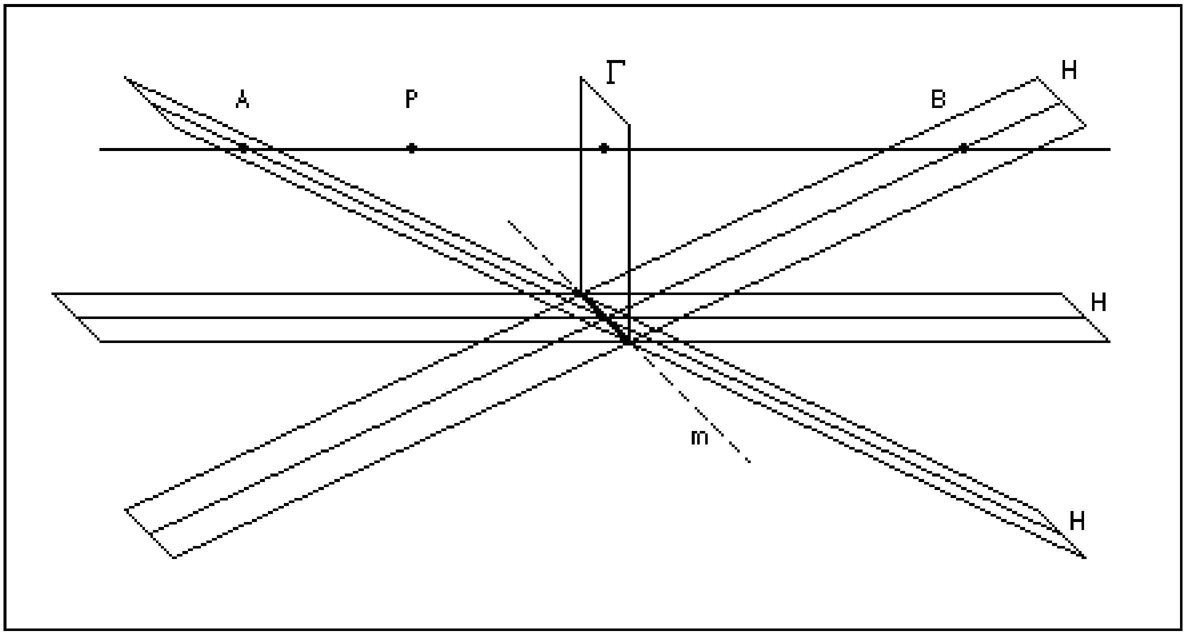
Figure 3



To obviate such irksome exceptions, projective geometry added to each straight line in space an ideal point, shared by every line parallel to it. Continuity requires then that all ideal points lie on a single ideal plane, which meets each family of parallel planes along a different ideal line. Fundamentalists may shudder at this seemingly wanton multiplication of entities. However, it had been practised in arithmetic for centuries, as the initial stock of natural numbers 1, 2, 3, ... , was supplemented with zero, the negative integers, the non-integral rationals, the irrationals, and the so-called imaginary numbers.

The points of a straight line stand in mutual relations of neighborhood and order. To see how the ideal point fits into these relations let H rotate continually about the straight line *m* where it intersects Γ. (See Figure 4.) When H is parallel to PQ---say, at time t---the projection of Q on H from P is the ideal point of the straight line through P and Q. Right before t the said projection is an ordinary point of H, very far from *m*. Right after t the projection is again an ordinary point of H, very far from *m*, but at the opposite end of the plane. Studying the continuous displacement of the projection during a short time interval surrounding t, one concludes that if A and B are any two points of H that stand, respectively, on either side of *m*, the ideal point of the straight line through A and B must be placed between A and B. Thus, in projective geometry, the points of a straight line are ordered cyclically, i.e., like the points of a circle. As a result of this, the neighborhood relations among points in projective space and on projective planes differ drastically from those familiar from standard geometry, and are highly counterintuitive. It is fair to say that projective geometry signified a much deeper and far-reaching revolution in human thought than did the mere denial of Euclid’s Postulate.

Figure 4



In the new setting, the projective properties of figures can be defined unexceptionably. A one-one mapping f of projective space onto itself is a *collineation* if it sends any three collinear points A, B, and C, to three points (A), (B), and (C), which are collinear too. Projective properties (and relations) are those which are preserved by collineations. Here are a few examples of projective properties. Of three or more points: to lie on the same straight line; to lie on the same plane. Of three or more straight lines: to meet at the same point; to lie on the same plane. Of three or more planes: to intersect along the same straight line; to share the same point. Of curves: to be a conic. Of surfaces: to be a quadric.

3. Klein's Erlangen program

In a booklet issued when he joined the faculty at Erlangen (1872), Felix Klein (b. 1849, d. 1925) took stock of the enormous growth and diversification of geometry and proposed a standpoint from which its many branches could be organized into a system. From this standpoint, the task of a branch of geometry can be stated thus:

> Given a manifold and a group of transformations of the manifold, to study the manifold configurations with respect to those features which are not altered by the transformations of the group. (Klein 1893, p. 67)

In nineteenth-century mathematics, 'manifold' often designated what we now call a set, but Klein apparently had something more specific in mind:

> If *n* variables $x_1, \ldots, x_n$ are given, the ... value systems we obtain if we let the variables x independently take the real values from $-\infty$ to $+\infty$ constitute what we shall call ... *a manifold of n dimensions*. Each particular value system $(x_1, \ldots, x_n)$ is called an *element* of the manifold. (Klein 1873, p. 116)

If *S* is a manifold in either sense, by a *transformation of S* we mean a one-one mapping of *S* onto itself. It is clear that

> (i) If T_1 and T_2 are transformations of *S*, the composite mapping $T_2 \circ T_1$, which consists of T_1 followed by T_2, is also a transformation of *S*;
>
> (ii) the composition of transformations is associative, so that, if T_1, T_2 and T_3 are transformations of *S*, $(T_3 \circ T_2) \circ T_1 = T_3 \circ (T_2 \circ T_1)$;
>
> (iii) the identity mapping I that sends each point of *S* to itself is a transformation of *S* such that, for any transformation T, $T \circ I = I \circ T = T$;
>
> (iv) for every transformation T there is a transformation T^{-1}, the *inverse* of T, such that $T^{-1} \circ T = I$ (T^{-1} sends each point of *S* back to where it was brought from by T).

By virtue of conditions (i)-(iv), the transformations of *S* form a *group* G_S in the precise sense that this term has in algebra. G_S includes subgroups, i.e., subsets which contain I and satisfy conditions (i) and (iv). If H is a subgroup of G_S and Φ is a feature of *S*, or of its elements or parts, which is not affected by the transformations of Φ, we say that Φ is H-invariant. The only G_S-invariant is the cardinality of *S* (i.e., the number of elements in the manifold). On the other hand, the group {I}, consisting of the identity alone, trivially preserves every conceivable feature. Between these two extremes there can be many different subgroups with all sorts of interesting invariants, depending on the respective group structure. If *S* is not an arbitrary (structureless) set, but a numerical manifold as described by Klein, it inherits structure from the real number field, which contributes to characterize the different subgroups of G_S and their invariants. Thus, the group of continuous transformations preserves the topological properties (neighborhood relations), and the group of linear transformations preserves the projective properties.

Can metric properties be fixed in this way? Traditionally one defines the distance between two points $(x_1, ... ,x_n)$ and $(y_1, ... ,y_n)$ of a numerical manifold as the positive square root of $(x_1 - y_1)^2 + ... + (x_n - y_n)^2$. The group of isometries consists of the transformations that preserve this function. However, this is no more than a convention, adopted to ensure that the geometry is Euclidean. Using projective geometry, Klein thought of something better. No real-valued function of point pairs, defined on all projective space, can be an invariant of the projective group, but there is a function of collinear point quadruples, called the cross-ratio, which is such an invariant. Drawing on work by Arthur Cayley (b. 1821, d. 1895), Klein (1871, 1873) employed the cross-ratio for defining projectively invariant distance functions on specific regions of projective space. Surprisingly, two of the three distance functions defined by Klein agree respectively, on their respective regions, with the distance functions of Euclid and Lobachevsky, while the third one determines another variety of non-Euclidean geometry which Klein dubbed ‘elliptic’. (In elliptic geometry every straight line meets every other, and the three internal angles of a triangle always

add up to more than two right angles. Klein’s names for the geometries of Euclid and Lobachevsky were ‘parabolic’ and ‘hyperbolic’, respectively.)

This is how Klein’s approach works for Lobachevskian geometry on the plane. Let κ be a real conic---a conic comprising only real points---on the projective plane. Let $G\kappa$ be the set of all collineations that map κ onto itself. $G\kappa$ is a subgroup of the projective group. Consider now the cross-ratio of point quadruples $<P_1,P_2,P_3,P_4>$ such that P_3 and P_4 belong to κ, while P_1 and P_2 range over the interior Int(κ) of κ. ($P \in$ Int(κ) if and only if P is a real point and no real tangent to κ passes through P.) P_3 and P_4 are the points where the straight line through P_1 and P_2 meets κ, so the said cross-ratio may be regarded as a function of the point pair $<P_1,P_2>$, say, $f\kappa(P_1,P_2)$. The function $f\kappa$ is clearly $G\kappa$-invariant. Put $d\kappa(P_1,P_2) = c \log f\kappa(P_1,P_2)$, where *c* is an arbitrary real-valued constant, different from 0, and log x denotes the principal value of the natural logarithm of x. Klein was able to show that $d\kappa$ behaves precisely like a Lobachevskian distance function on Int(κ). In other words, every theorem of Lobachevskian geometry holds for suitable figures formed from points of Int(κ), if the distance between any two of these points is given by the function $d\kappa$. Consider, for instance, four points P_1,P_2,P_3, and P_4 in Int(κ), such that $d\kappa(P_1,P_2) = d\kappa(P_2,P_3) = d\kappa(P_3,P_4) = d\kappa(P_4,P_1)$. They are the vertices of a Lobachevskian equilateral quadrilateral Q, which can have at most three right angles, in which case the fourth interior angle of Q must be acute. (Where ‘right angle’ means, as usual, an angle equal to its adjacent angle, and two angles in Int(κ) are said to be equal if one is the image of the other by a transformation of group $G\kappa$).

If κ stands for a different sort of conic, not an ordinary real one, the function $d\kappa$ obtained by the above procedure behaves on suitably defined regions of the projective plane like a Euclidian distance function or like the distance function of elliptic geometry (this depends on the nature of the conic κ). Thus, depending on whether κ belongs to one or the other of three kinds of conic, the group of collineations that map κ onto itself is structurally identical with one of the three groups of Lobachevskian, Euclidean, or elliptic isometries. Similar results hold for the three-dimensional case, with κ a quadric surface.

Klein’s result led Bertrand Russell (b. 1873, d. 1970) to assert, in his neo-Kantian book on the foundations of geometry (1897), that the general "form of externality" is disclosed to us a priori in projective geometry, but its metric structure---which can *only* be Lobachevskian, Euclidean or elliptic---must be determined a posteriori by experiment. Henri Poincaré (b. 1854, d. 1912) took a more radical stance: If geometry is nothing but the study of a group,

> one may say that the truth of the geometry of Euclid is not incompatible with the truth of the geometry of Lobachevsky, for the existence of a group is not incompatible with that of another group. (Poincaré 1887, p. 290)

The application to physics is immediate: "Among all possible groups we have chosen one in particular, in order to refer to it all physical phenomena, just as we choose three coordinate axes in order to refer to them a geometrical figure" (ibid., p. 291). The choice of this particular group is motivated by its mathematical simplicity, but also by the fact that "there exist in nature some remarkable bodies which are

called *solids*, and experience tells us that the different possible movements of these bodies are related to one another much in the same way as the different operations of the chosen group" (ibid.).

Klein's group-theoretical view of geometry enjoyed much favor among mathematicians and philosophers. It achieved a major success when Minkowski (1909) showed that the gist of Einstein's special theory of relativity was the (spacetime) geometry of the Lorentz group. But Klein's Erlangen program failed to cover the differential geometry of Riemann (§5), which Einstein (1915, 1916) placed at the core of his general theory of relativity.

4. Axiomatics perfected

According to Aristotle, scientific knowledge (*episteme*) must be expressed in statements that follow deductively from a finite list of self-evident statements (axioms) and only employ terms defined from a finite list of self-understood terms (primitives). For over two millennia it was taken for granted that Aristotle's ideal is actually realized in Euclid's *Elements*. In fact, there is a logical gap already in Euclid I.1 (the solution of this problem rests on an unstated assumption of continuity) and it is not clear that Euclid regarded his postulates as self-evident (by calling them "requests" he suggested he did not). The idea of securing knowledge by logical deduction from unquestionable principles had a powerful fascination for modern scientists such as Galileo and Newton, both of whom fondly practised axiomatics, at any rate as a literary form, like Spinoza in his *Ethics*. Still, a truly satisfactory and, if one may say so, serious instance of axiomatization of a branch of knowledge was not available in print until 1882, when Moritz Pasch (b. 1843, d. 1930) published his *Lectures on Modern Geometry*.

Pasch viewed geometry as a natural science, whose successful utilization by other sciences and in practical life rests "exclusively on the fact that geometrical concepts originally agreed exactly with empirical objects" (Pasch 1882, p. iii). Geometry distinguishes itself from other natural sciences because it obtains only very few concepts and laws directly from experience, and aims at obtaining from them the laws of more complex phenomena by purely deductive means. The empirical foundation of geometry was encapsulated by Pasch in a core of basic concepts and basic statements or axioms. The basic concepts refer to the shape, size and reciprocal position of bodies. They are not defined, for no definition could replace the "exhibition of appropriate natural objects," which is the only road to understanding such simple, irreducible notions (ibid., p. 16). All other geometric concepts must be ultimately defined in terms of the basic ones. The basic concepts are connected to one another by the axioms, which "state what has been observed in certain very simple diagrams" (p. 43). All other geometric statements must be proved from the axioms by the strictest deductive methods. Everything that is needed to prove them must be recorded, without exception, in the axioms. These must therefore embody the whole empirical material elaborated by geometry, so that "after they are established it is no longer necessary to resort to sense perceptions" (p. 17). "Every conclusion which occurs in a proof must find its confirmation in the diagram, but it is not justified by the diagram, but by a definite earlier statement (or definition)" (p. 43). Pasch understood clearly the implications of his method. He writes (p. 98):

> If geometry is to be truly deductive, the process of inference must be independent in all its

> parts from the *meaning* of the geometric concepts, just as it must be independent from the diagrams. All that need be considered are the *relations* between the geometric concepts, recorded in the statements and definitions. In the course of deduction it is both permitted and useful to bear in mind the meaning of the geometric concepts that occur in it, but *it is not at all necessary*. Indeed, when it actually beomes necessary, this shows that there is a gap in the proof, and---if the gap cannot be eliminated by modifying the argument---that the premises are too weak to support it.

Pasch's *Lectures on Modern Geometry* dealt with projective geometry. The first rigorous axiomatization of Euclidean geometry---*Foundations of Geometry* by David Hilbert (b. 1862, d. 1943)---appeared in 1899 and exercised enormous influence on twentieth century mathematics and philosophy. Hilbert invites the reader to consider three arbitrary collections of objects, which he calls 'points', 'straight lines' and 'planes', and five undefined relations between (i) a point and a straight line, (ii) a straight line and a plane, (iii) three points, (iv) two pairs of points ('segments') and (v) two equivalence classes of point triples ('angles'). The conditions prescribed in Hilbert's 20 axioms---including the Axiom of Completeness added in the second edition---are sufficient to characterize the said objects and relations up to isomorphism. Isomorphism---i.e., structural equivalence---can hold, however, between different, intuitively disparate, systems of objects. Hilbert availed himself of this feature of axiomatic theories for studying the independence of some axioms from the rest. To prove it he proposed actual instances (models) of the structure determined by all axioms but one, plus the negation of the omitted one. Frege complained that the geometric axioms retained in these exercises could be applied to Hilbert's far-fetched models only by tampering with the natural meaning of words (cf. Alice's conversation with Humpty Dumpty). Hilbert replied on 29 December 1899:

> Every theory is only a scaffolding or schema of concepts together with their necessary mutual relations, and the basic elements can be conceived in any way you wish. If I take for my points any system of things, for example, the system love, law, chimney-sweep, ... and I just assume all my axioms as relations between these things, my theorems---for example, the theorem of Pythagoras---also hold of these things. ... This feature of theories can never be a shortcoming and is in any case inevitable.

All this follows, of course, from the very nature of axiomatics, as explained in the passage quoted from Pasch. Indeed, such truth-preserving semantic permutations were no news in geometry after Gergonne (1771-1859) drew attention in 1825 to the following *principle of duality:* Any true statement of projective plane geometry gives rise to another, equally true, dual statement obtained by substituting 'point' for 'line', 'collinear' for 'concurrent', 'meet' for 'join', and vice versa, wherever these words occur in the former. (In projective space geometry, duality holds for points and planes.) The same result is secured, of course, by exchanging not the words, but their meanings.

5. The differential geometry of Riemann

In a lecture "On the hypotheses that lie at the foundation of geometry", delivered to the Faculty of

Philosophy at Göttingen in 1854 and posthumously published in 1867, Bernhard Riemann (b. 1826, d. 1866) presented some radically innovative views on this matter. He noted that the measurable properties of a discrete manifold can be readily determined by counting. (Think of the population of a country, and such properties as the median, average and aggregate income, or the proportion of drug-addicts and born-again Christians.) But continuous manifolds do not admit this approach. In particular, the metric properties of physical space, which are the subject of geometry, must depend on the binding forces that act on it. The distance between two points in space can be ascertained with a rod, or a tape, or by optical means, and the result depends essentially on the physical behavior of the instruments used. Up to now, the metric properties of space have been successfully described in accordance with Euclidean geometry. However, "the empirical concepts on which the metric determinations of space are based --- the concepts of a rigid body and a light ray--- lose their validity in the infinitely small; it is therefore quite likely that the metric relations of space in the infinitely small do not agree with the assumptions of geometry, and in fact one would have to accept this as soon as the phenomena can thereby be explained in a simpler way" (Riemann 1854, p. 149). To prepare physicists for this eventuality, Riemann proposed a more general conception of geometry. Riemann's basic scheme makes allowance for much greater generality than he actually reaches for; but, in his judgment, it should be enough for the time being to characterize the geometry of continuous manifolds in such a way that it agrees optimally with Euclidean geometry on a small neighborhood of each point.

Riemann extends to *n* dimensions the methods employed by Gauss (1828) in his study of the intrinsic geometry of curved surfaces embedded in Euclidean space (called "intrinsic" because it describes the metric properties that the surfaces display by themselves, independently of the way they lie in space). Looking back at Gauss's work one gets a better intuitive feel for Riemann's concepts (see Torretti 1978, pp. 68-82). However, for the sake of conciseness and perspicuity, it is advisable to look forward and to avail oneself of certain concepts introduced by later mathematicians as they tried to make sense of Riemann's proposal. Consider the following modern formulation of Riemann's theory, in this Supplement.

In his study of curved surfaces, Gauss introduced a real-valued function, the *Gaussian curvature*, which measures a surface's local deviation from flatness in terms of the surface's intrinsic geometry. Riemann extended this concept of curvature to Riemannian n-manifolds. By using his extended concept of curvature, he was able to characterize with great elegance the metric manifolds in which all figures can freely move around without changing their size and shape. They are the Riemannian manifolds of *constant curvature*. This idea can be nicely combined with Klein's classification of metric geometries. Regarded as Riemannian 3-manifolds, Euclidean space has constant zero curvature, Lobachevskian space has constant negative curvature, and elliptic space has constant positive curvature. Pursuant to the Erlangen Program, each of these geometries of constant curvature is characterized by its own group of isometries. But Klein's conception is too narrow to embrace all Riemannian geometries, which include spaces of variable curvature. Indeed, in the general case, the group of isometries of a Riemannian n-manifold is the trivial group consisting of the identity alone, whose structure conveys no information at all about the respective geometry.

Supplement to Nineteenth Century Geometry

A Modern Formulation of Riemann’s Theory

The multidimensional continua that Riemann was concerned with are essentially instances of what is now known as a real *n-dimensional smooth manifold*. For brevity, call them ‘n-*manifolds*’. (For example, a sphere, a Möbius strip and the surface of a Henry Moore sculpture may be regarded as 2-manifolds; the spacetimes models of current cosmology are 4-manifolds.) Conditions (a) -- (c) provide a full characterization of n-manifolds.

> (a) An n-manifold **M** is a set of points that can be pieced together from partially overlapping patches, such that every point of **M** lies in at least one patch.
>
> (b) **M** is endowed with a neighborhood structure (a topology) such that, if U is a patch of **M**, there is a continuous one-one mapping *f* of U onto some region of $\mathbf{R}^n$, with continuous inverse f^{-1}. ($\mathbf{R}^n$ denotes here the collection of all real number n-tuples, with the standard topology generated by the open balls.) *f* is a coordinate system or *chart* of **M**; the k-th number in the n-tuple assigned by a chart *f* to a point P in *f*’s patch is called the k-th coordinate of P by *f*; the k-th coordinate function of chart *f* is the real-valued function that assigns to each point of the patch its k-th coordinate by *f*.
>
> (c) There is a collection **A** of charts of **M**, which contains at least one chart defined on each patch of **M** and is such that, if g and h belong to **A**, the composite mappings $h \circ g^{-1}$ and $g \circ h^{-1}$ --- known as *coordinate transformations* --- are differentiable to every order wherever they are well defined. (Denote the real number n-tuple $<a_1, \ldots , a_n>$ by **a**. The mapping $h \circ g^{-1}$ is well defined at **a** if **a** is the valued assigned by g to some point P of **M** to which h also assigns a value. Suppose that the latter value $h(P) = <b_1, \ldots ,b_n> = \mathbf{b}$; then, $\mathbf{b} = h \circ g^{-1}(\mathbf{a})$. Since $h \circ g^{-1}$ maps a region of $\mathbf{R}^n$ into $\mathbf{R}^n$, it makes sense to say that $h \circ g^{-1}$ is differentiable.) Such a collection **A** is called an *atlas*.[*]

It is the pair $<\mathbf{M}, \mathbf{A}>$ that, strictly speaking, is an n-manifold, in the sense defined above. If $<\mathbf{M}_1,\mathbf{A}_1>$ and $<\mathbf{M}_2,\mathbf{A}_2>$ are an n-manifold and an m-manifold, respectively, it makes good sense to say that a mapping *f* of $\mathbf{M}_1$ into $\mathbf{M}_2$ is differentiable at a point P of $\mathbf{M}_1$ if, for a chart h defined at P and a chart g defined at *f*(P), the composite mapping $g \circ f \circ h^{-1}$ is differentiable at h(P). (Condition (c) implies that the fulfillment of this requirement does not depend on the choice of h and g.) *f* is differentiable if it is differentiable at every point of $\mathbf{M}_1$.

Let <**M**,**A**> be an n-manifold. To each point P of **M** one associates a vector space, which is known as the *tangent space at P* and is denoted by T_P**M**. The idea is based on the intuitive notion of a plane tangent to a surface at a given point. It can be constructed as follows. Let γ be a one-one differentiable mapping of a real open interval **I** into **M**. We can think of the successive values of γ as forming the path of a point that moves through **M** during a time interval represented by **I**. We call γ a *curve* in **M** (parametrized by u $\in$ **I**). Put $\gamma(t_0)$ = P for a fixed number t_0 in **I**. Consider the collection **F**(P) of all differentiable real-valued functions defined on some neighborhood of P. With the ordinary operations of function addition and multiplication by a constant, **F**(P) has the structure of a vector space. Each function *f* in **F**(P) varies smoothly with u, along the path of γ, in some neighborhood of P. Its rate of variation at P = $\gamma(t_0)$ is properly expressed by the derivative $d(f\circ\gamma)/du$ at u = t_0. As *f* ranges over **F**(P), the value of $d(f\circ\gamma)/du$ at u = t_0 is apt to vary in **R**. So we have here a mapping of **F**(P) into **R**, which we denote by $\dot{\gamma}(u)$. It is in fact a linear function and therefore a vector in the dual space **F***(P) of real-valued linear functions on **F**(P). Call it the *tangent* to γ at P. The tangents at P to all the curves whose paths go through P span an n-dimensional subspace of **F***(P). This subspace is, by definition, the tangent space T_P**M**. The tangent spaces at all points of an n-manifold **M** can be bundled together in a natural way into a 2n-manifold T**M**. The projection mapping π of T**M** onto **M** assigns to each tangent vector **v** in T_P**M** the point π(**v**) at which **v** is tangent to **M**. The structure <T**M**,**M**,π> is the tangent bundle over **M**. A vector field on **M** is a section of T**M**, i.e., a differentiable mapping ***f*** of **M** into T**M** such that $\pi \circ$ ***f*** sends each point P of **M** to itself; such a mapping obviously assigns to P a vector in T_P**M**.

Any vector space **V** is automatically associated with other vector spaces, such as the dual space **V*** of linear functions on **V**, and the diverse spaces of multilinear functions on **V**, on **V***, and on any possible combination of **V** and **V***. This holds, of course, for each tangent space of an n-manifold **M**. The dual of T_P**M** is known as the cotangent space at P. There is a natural way of bundling together the cotangent spaces of **M** into a 2n-manifold, the cotangent bundle. Generally speaking, all the vector spaces of a definite type associated with the tangent and cotangent spaces of **M** can be naturally bundled together into a k-manifolds (for suitable integers k, depending on the nature of the bundled items). A section of any of these bundles is a *tensor field* on **M** (of rank r, if the bundled objects are r-linear functions).

A *Riemannian metric* **g** on the n-manifold <**M**,**A**> is a tensor field of rank 2 on **M**. Thus, **g** assigns to each P in **M** a bilinear function $\mathbf{g}_P$ on T_P**M**. For any P in **M** and any vectors **v**, **w**, in T_P**M**, $\mathbf{g}_P$ must meet these requirements:

(i) $\mathbf{g}_P(\mathbf{v},\mathbf{w}) = \mathbf{g}_P(\mathbf{w},\mathbf{v})$ (symmetry)

(ii) $\mathbf{g}_P(\mathbf{v},\mathbf{w}) = 0$ for all vectors **w** in T_P**M** if and only if **v** is the 0-vector (non-degeneracy)

(iii) $\mathbf{g}_P(\mathbf{v},\mathbf{v}) > 0$ unless **v** is the 0-vector (positive definiteness).

It is worth noting that the so-called Lorentzian metrics defined by relativity theory on its spacetime models meet requirements (i) and (ii), but not (iii), and are therefore usually said to be *semi-Riemannian*.

The length $\lambda(\mathbf{v})$ of a vector **v** in $T_P\mathbf{M}$ is defined by $|\lambda(\mathbf{v})|^2 = \mathbf{g}_P(\mathbf{v},\mathbf{v})$. Let γ be a curve in **M**. Let $\dot{\gamma}(u)$ be the tangent to γ at the point $\gamma(u)$. The length of γ's path from $\gamma(a)$ to $\gamma(b)$ is measured by the integral

$$\int_a^b \lambda(\dot{\gamma}(u))du$$

Thus, in Riemannian geometry, the length of the tangent vector $\dot{\gamma}(u)$ bears witness to the advance of curve g as it passes through the point $\gamma(u)$. The definition of the length of a curve leads at once to the notion of a geodesic (or straightest) curve, which is characterized by the fact that its length is extremal; in other words, a geodesic is either the greatest or the shortest among all the curves that trace out neighboring paths between the same two points.

In his study of curved surfaces, Gauss introduced a real-valued function, the *Gaussian curvature*, which measures a surface's local deviation from flatness in terms of the surface's intrinsic geometry. Riemann extended this concept of curvature to Riemannian n-manifolds. He observed that each geodesic through a point in such a manifold is fully determined by its tangent vector at that point. Consider a point P in a Riemannian n-manifold <**M**,**A**,**g**> and two linearly independent vectors **v** and **w** in $T_P\mathbf{M}$. The geodesics determined by all linear combinations of **v** and **w** form a 2-manifold about P, with a definite Gaussian curvature $K_P(\mathbf{v},\mathbf{w})$ at P. The real number $K_P(\mathbf{v},\mathbf{w})$ measures the curvature of **M** at P in the 'surface direction' (Riemann 1854, p. 145) fixed by **v** and **w**. Riemann (1861) thought up a global mapping, depending on the metric **g**, that yields the said values $K_P(\mathbf{v},\mathbf{w})$ on appropriate arguments P, **v** and **w**. Nowadays this object is conceived as a tensor field of rank 4, which assigns to each point P in a Riemannian n-manifold <**M**,**A**,**g**> a 4-linear function on the tangent space $T_P\mathbf{M}$. It is therefore known as the *Riemann tensor*. Given the above definition of $K_P(\mathbf{v},\mathbf{w})$ it is clear that, if n = 2, the Riemann tensor reduces to the Gaussian curvature function.

Notes to Supplement: A Modern Formulation of Riemann's Theory

---

Notes

* The informal characterization of n-manifolds in the supplement is not altogether accurate and may cover some far-fetched monsters that we do not wish to cover with this concept. For readers who have a smattering of topology the following characterization is preferable.

> (a) Let **M** be a set of points. Pick a collection of partially overlapping subsets of **M**, or *patches*, such that every point of **M** lies in at least one patch.
>
> (b) If U is a patch of M, there is a one-one mapping *f* of U onto an open space of $\mathbf{R}^n$, whose inverse we denote by f^{-1}. ($\mathbf{R}^n$ denotes here the collection of all real number n-tuples, with the standard topology generated by the open balls.) f is a coordinate system or *chart* of **M**; the k-th number in the n-tuple assigned by a chart *f* to a point P in *f*'s domain is called the k-th coordinate of P by *f*; the k-th coordinate function of chart *f* is the real-valued function that assigns to each point of the patch its k-th coordinate by *f*.
>
> (c) There is a collection **A** of charts of **M** which contains at least one chart defined on each patch of **M** and is such that, if g and h belong to **A**, the composite mappings $h \circ g^{-1}$ and $g \circ h^{-1}$ --- known as *coordinate transformations* --- are differentiable to every order wherever they are well defined. (Denote the real number n-tuple $(a_1, \ldots, a_n)$ by **a**. $h \circ g^{-1}$ is well defined at **a** if **a** is the valued assigned by g to some point P of **M** to which h also assigns a value. Suppose that the latter value $h(P) = (b_1, \ldots, b_n) = \mathbf{b}$; then, $\mathbf{b} = h \circ g^{-1}(\mathbf{a})$. Since $h \circ g^{-1}$ maps a region of $\mathbf{R}^n$ into $\mathbf{R}^n$, it makes sense to say that $h \circ g^{-1}$ is differentiable.) Such a collection **A** is called an *atlas* for **M**.
>
> (d) A given atlas **A** for **M** can be extended in one and only one way to a maximal atlas $\mathbf{A}_{max}$ as follows: add to **A** every one-one mapping g of a subset of **M** onto an open set of $\mathbf{R}^n$ which, combined with any chart h of **A**, satisfies the condition of differentiability stated under (c).
>
> (e) **M** is given the weakest Hausdorff topology that makes every chart g in $\mathbf{A}_{max}$ into a homeomorphism. (A topological space is said to be Hausdorff if any two points in it have open neighborhoods that do not overlap.)

The pair (**M**,**A**) is an n-manifold.

Education

Ph.D., Philosophy, University of Freiburg, Germany, 1954
(Thesis Director: Wilhelm Szilasi)

Areas of Specialization

Philosophy of physics, especially relativity theory

Philosophy of mathematics, especially 19th century geometry

Professional Experience

- Professor of Philosophy,
  Universidad de Chile (1999 -- present)
- Professor of Philosophy,
  University of Puerto Rico (1970 -- 1995)
- Editor, *Dialogos* (1971 -- 1995)
- Professor of Philosophy,
  Universidad de Chile (1964 -- 1970)
- Director, Centro de Estudios Humanisticos,
  Faculty of Physics and Mathematics,
  Universidad de Chile (1964 -- 1970)
- Professor of Philosophy,
  Universidad de Concepcion, Chile (1961-- 1964)
- Chairman, Department of Philosophy,
  Universidad de Concepcion, Chile (1961 -- 1964)
- Lecturer, Faculty of General Studies,
  University of Puerto Rico (1958 -- 1961)
- Translator, Secretariat,
  United Nations, New York City(1955 -- 1958)

Academic Awards:

- Fellow, Pittsburgh Center for the Philosophy of Science, 1983-1984
- John Simon Guggenheim Memorial Fellow, 1980-1981
- John Simon Guggenheim Memorial Fellow, 1975-1976
- Alexander-von-Humboldt Dozentenstipendiat, Kant-Archiv, Bonn, 1964-1965

Learned Societies

- Institut International de Philosophie
- Academie Internationale de Philosophie des Sciences

Substructural Logics

Substructural logics are non-classical logics *weaker* than classical logic, notable for the absence of *structural rules* present in classical logic. These logics are motivated by considerations from philosophy (relevant logics), linguistics (the Lambek calculus) and computing (linear logic). In addition, techniques from substructural logics are useful in the study of traditional logics such as classical and intuitionistic logic. This article provides a brief overview of the field of substructural logic. For a more detailed introduction, complete with theorems, proofs and examples, the reader can consult the books and articles in the Bibliography.

Residuation

Logic is about *logical consequence*. As a result, the *conditional* is a central notion in logic because of its intimate connection with logical consequence. This connection is neatly expressed in *residuation condition*:

$$p, q \vdash r \quad \text{if and only if} \quad p \vdash q \rightarrow r$$

It says that r follows from p together with q just when $q \rightarrow r$ follows from p alone. The validity of the transition from q to r (given p) is recorded by the conditional $q \rightarrow r$. (It is called residuation by analogy with residuation in mathematics. Consider the connection between addition and substraction. $a + b = c$ if and only if $a = c - b$. The resulting a (which is $c - b$) is the *residual*, what is left of c when b is taken away.)

However, there is one extra factor in the equation. Not only is there the turnstile, for logical consequence, and the conditional, encoding consequence inside the language of propositions, there is also the *comma*, indicating the *combination* of premises. The behaviour of premise combination is also important in determining the behaviour of the conditional. As the comma's behaviour varies, so does the conditional. In this introduction we will see how this comes about.

Weakening

It is one thing for p to be true. It is another for the conditional $q \rightarrow p$ to be true. Yet, if '$\rightarrow$' is a material conditional, $q \rightarrow p$ follows from p. It seems worthwhile to understand how a conditional might work in the *absence* of this inference. This is tied to the behaviour of premise combination, as can be shown by this demonstration.

$$\frac{\dfrac{p \vdash p}{p, q \vdash p}}{p \vdash q \rightarrow p}$$

From the axiomatic $p \vdash p$ (anything follows from *itself*) we deduce that p follows from p together with q, and then by the residuation condition, $p \vdash q \rightarrow p$. Given that we accept the residuation condition, and the identity axiom at the start of the proof, we must reject the first step in the proof if we are to deny that $q \rightarrow p$ follows from p. This rule, which has the general form:

$$\frac{X \vdash A}{X, Y \vdash A}$$

is called the rule of *weakening*. We step from a stronger statement, that A follows from X to a possibly weaker one, that A follows from X together with Y.

This rule may fail, given different notions of premise combination (the notion encoded by the comma in X,Y). If the conditional $\rightarrow$ is *relevant* (if to say that $p \rightarrow q$ is true is to say, at least, that q truly *depends* on p) then the comma will not satisfy weakening. We may indeed have A following from X, without A following from X,Y, for it need not be the case that A depends on X and Y together.

In relevant logics the rule of weakening fails on the *other* side too, in that we wish *this* argument to be invalid too:

$$q \vdash q$$

$$p, q \vdash q$$

$$p \vdash q \rightarrow q$$

Again, q may follow from q, but this doesn't mean that it follows from *p together with q*, provided that "together with" is meant in an appropriately strong sense. So, in relevant logics, the inference from an arbitrary premise to a logical truth such as $q \rightarrow q$ may well fail.

Commutativity

If the mode of premise combination is commutative (if anything which follows from X, Y also follows from Y, X) then we can reason as follows, using just the identity axiom and residuation:

$$p \rightarrow q \vdash p \rightarrow q$$

$$p \rightarrow q, p \vdash q$$

$$p, p \rightarrow q \vdash q$$

$$p \vdash (p \rightarrow q) \rightarrow q$$

In the absence of commutativity of premise combination, this proof is not available. This is another simple example of the connection between the behaviour of premise combination and that of the conditional.

There are many kinds of conditional for which this inference fails. If $\rightarrow$ has *modal* force (read it as *entails*) then we may have p without also having $(p \rightarrow q) \rightarrow q$. It may be true that Greg is a logician (p) and it is true that Greg's being a logician entails Greg's being a philosopher ($p \rightarrow q$) but this does not *entail* that Greg is a philosopher. (There are many possibilities in which the entailment ($p \rightarrow q$) is true but q is not.) So we have p true but $(p \rightarrow q) \rightarrow q$ is not true.

This makes sense when we consider premise combination. Here when we say $X,A \vdash B$ is true, we are not just saying that B follows when we put X and A together. If we are after a genuine *entailment* $A \rightarrow B$, then we want B to be true in any (related) possibility in which A is true. So, $X,A \vdash B$ says that in *any* possibility in which A is true, so is B. These possibilities mightn't satisfy all of X. (In classical theories of entailment, the possibilities are those in which all that is taken as *necessary* in X are true.)

If premise combination is not commutative, then residuation can go in *two* ways. In addition to the

residuation condition giving the behaviour of $\rightarrow$, we may wish to define a new arrow $\leftarrow$ as follows:

$p, q \vdash r$ if and only if $q \vdash r \leftarrow p$

For the left-to-right arrow we have *modus ponens* in this direction:

$p \rightarrow q, p \vdash q$

For the right-to-left arrow, *modus ponens* is provable with the premises in the opposite order:

$p, q \leftarrow p \vdash q$

This is a characteristic of substructural logics. When we pay attention to what happens when we don't have the full complement of structural rules, then new possibilities open up. We uncover *two* conditionals underneath what was previously one (in intuitionistic or classical logic).

Associativity

Here is another way that structural rules influence proof. The associativity of premise combination provides the following proof:

$$\dfrac{\dfrac{\dfrac{\dfrac{p \rightarrow q, p \vdash q \qquad r \rightarrow p, r \vdash p}{p \rightarrow q, (r \rightarrow p, r) \vdash q}}{(p \rightarrow q, r \rightarrow p), r \vdash q}}{p \rightarrow q, r \rightarrow p \vdash r \rightarrow q}}{p \rightarrow q \vdash (r \rightarrow p) \rightarrow (r \rightarrow q)}$$

This proof uses the *cut* rule at the topmost step. The idea is that inferences can be combined. If $X \vdash A$ and $Y(A) \vdash B$ (where $Y(A)$ is a structure of premises possibly including A one or more times) then $Y(X) \vdash B$ too (where $Y(X)$ is that structure of premises with those instances of A replaced by X). In this proof, we replace the p in $p \rightarrow q, p \vdash q$ by $r \rightarrow p, r$ on the basis of the validity of $r \rightarrow p, r \vdash p$.

Contraction

A final important example is the rule of *contraction* which dictates how premises may be reused.

Contraction is crucial in the inference of $p \rightarrow q$ from $p \rightarrow (p \rightarrow q)$

$$
\dfrac{\dfrac{\dfrac{p \rightarrow (p \rightarrow q) \vdash p \rightarrow (p \rightarrow q)}{p \rightarrow (p \rightarrow q), p \vdash p \rightarrow q} \quad \dfrac{p \rightarrow q \vdash p \rightarrow q}{p \rightarrow q, p \vdash q}}{(p \rightarrow (p \rightarrow q), p), p \vdash q}}{\dfrac{p \rightarrow (p \rightarrow q), p \vdash q}{p \rightarrow (p \rightarrow q) \vdash p \rightarrow q}}
$$

These different examples give you a taste of what can be done by structural rules. Not only do structural rules influence the conditional, but they also have their effects on other connectives, such as conjunction and disjunction (as we shall see below) and negation (Dunn 1993; Restall 2000).

Logics in the Family

There are many different formal systems in the family of substructural logics. These logics can be motivated in different ways.

Relevant Logics

Many people have wanted to give an account of logical validity which pays some attention to conditions of *relevance*. If $X,A \vdash B$ holds, then X must somehow be *relevant* to A. Premise combination is restricted in the following way. We may have $X \vdash A$ without also having $X,Y \vdash A$. The new material Y might not be relevant to the deduction. In the 1950s, Moh (1950), Church (1951) and Ackermann (1956) all gave accounts of what a "relevant" logic could be. The ideas have been developed by a stream of workers centred around Anderson and Belnap, their students Dunn and Meyer, and many others. The canonical references for the area are Anderson, Belnap and Dunn's two-volume *Entailment* (1975 and 1992). Other introductions can be found in Read's *Relevant Logic* and Dunn's "Relevance Logic and Entailment" (1986). A more polemical introduction and defence of relevant logics can be found in Routley, Plumwood, Meyer and Brady's *Relevant Logics and Their Rivals*.

Resource Consciousness

This is not the only way to restrict premise combination. Girard (1987) introduced *linear logic* as a model for processes and resource use. The idea in this account of deduction is that resources must be used (so premise combination satisfies the relevance criterion) and they do not extend *indefinitely*.

Premises cannot be *re*-used. So, I might have $X,X \vdash A$, which says that I can use X twice to get A. I might not have $X \vdash A$, which says that I can use X once alone to get A. A helpful introduction to linear logic is given in Troelstra's *Lectures on Linear Logic* (1992). There are other formal logics in which the *contraction rule* (from $X,X \vdash A$ to $X \vdash A$) is absent. Most famous among these are Lukasiewicz's many-valued logics. There has been a sustained interest in logics without this rule because of Curry's paradox (Curry 1977, Geach 1995; see also Restall 1994 in Other Internet Resources).

Order

Independently of either of these traditions, Joachim Lambek considered mathematical models of language and syntax (Lambek 1958, 1961). The idea here is that premise combination corresponds to composition of strings or other linguistic units. Here X,X differs in content from X, but in addition, X,Y differs from Y,X. Not only does the *number* of premises used count but so does their *order*. Good introductions to the Lambek calculus (also called *categorial grammar*) can be found in books by Moortgat (1988) and Morrill (1994).

Proof Systems

We have already seen a fragment of one way to present substructural logics, in terms of proofs. We have used the residuation condition, which can be understood as including two rules for the conditional, one to *introduce* a conditional

$$\frac{X, A \vdash B}{X \vdash A \to B}$$

and another to *eliminate* it.

$$\frac{X \vdash A \to B \qquad Y \vdash A}{X, Y \vdash B}$$

Rules like these form the cornerstone of a natural deduction system, and these systems are available for the wide sweep of substructural logics. But proof theory can be done in other ways. *Gentzen* systems operate not introducing and eliminating connectives, but by introducing them both on the left and the right of the turnstile of logical consequence. We keep the introduction rule above, and replace the elimination rule by one introducing the conditional on the left:

$$\frac{X \vdash A \qquad Y(B) \vdash C}{Y(A \rightarrow B, X) \vdash C}$$

This rule is more complex, but it has the same effect as the arrow elimination rule: It says that if *X* suffices for *A*, and if you use *B* (in some context *Y*) to prove *C* then you could just as well have used *A* → *B* together with *X* (in that same context *Y*) to prove *C*, since *A* → *B* together with *X* gives you *B*.

Gentzen systems, with their introduction rules on the left and the right, have very special properties which are useful in studying logics. Since connectives are always *introduced* in a proof (read from top to bottom) proofs never *lose* structure. If a connective does not appear in the conclusion of a proof, it will not appear in the proof at all, since connectives cannot be eliminated.

In certain substructural logics, such as linear logic and the Lambek calculus, and in the fragment of the relevant logic **R** without disjunction, a Gentzen system can be used to show that the logic is *decidable*, in that an algorithm can be found to determine whether or not an argument $X \vdash A$ is valid. This is done by searching for proofs of $X \vdash A$ in a Gentzen system. Since premises of this conclusion must feature no language not in this conclusion, and they have no greater complexity (in these systems), there are only a finite number of possible premises. An algorithm can check if these satisfy the rules of the system, and proceed to look for premises for these, or to quit if we hit an axiom. In this way, decidability of some substructural logics is assured.

However, not all substructural logics are decidable in this sense. Most famously, the relevant logic **R** is not decidable. This is partly because its proof theory is more complex than that of other substructural logics. **R** differs from linear logic and the Lambek calculus in having a straightforward treatment of conjunction and disjunction. In particular, conjunction and disjunction satisfy the rule of *distribution*:

$$p \mathbin{\&} (q \vee r) \vdash (p \mathbin{\&} q) \vee (p \mathbin{\&} r)$$

The natural proof of distribution in any proof system uses both weakening and contraction, so it is not available in the relevant logic **R**, which does not contain weakening. As a result, proof theories for **R** either contain distribution as a primitive rule, or contain a second form of premise combination (so called *extensional* combination, as opposed to the *intensional* premise combination we have seen) which satisfies weakening and contraction.

Semantics

While the relevant logic **R** has a proof system more complex than the substructural logics such as linear logic, which lack distribution of (extensional) conjunction over disjunction, its *semantics* is altogether more simple. A Routley-Meyer *model* for the relevant logic **R** is comprised of a set of *points P* with a

three-place relation R on P. A conditional $A \rightarrow B$ is evaluated at a world as follows:

> $A \rightarrow B$ is true at x if and only if for each y and z where $Rxyz$, if A is true at y, B is true at z.

An argument is *valid* in a model just when in any point at which the premises are true, so is the conclusion. The argument $A \vdash B \rightarrow B$ is invalid because we may have a point x at which A is true, but at which $B \rightarrow B$ is not. We can have $B \rightarrow B$ fail to be true at x simply by having $Rxyz$ where B is true at y but not at z.

The three place relation R follows closely the behaviour of the mode of premise combination in the proof theory for a substructural logic. For different logics, different conditions can be placed on R. For example, if premise combination is commutative, we place a *symmetry* condition on R like this: $Rxyz$ if and only if $Ryxz$. Ternary relational semantics gives us great facility to *model* the behaviour of substructural logics. (The extent of the correspondence between the proof theory and algebra of substructural logics and the semantics is charted in Dunn's work on *Gaggle Theory* (1991) and is summarised in Restall's *Introduction to Substructural Logics* (2000).) Furthermore, if conjunction and disjunction satisfy the distribution axiom mentioned in the previous section, they can be modelled straightforwardly too: a conjunction is true at a point just when both conjuncts are true at that point, and a disjunction is true at a point just when at least one disjunct is true there. For logics, such as linear logic, *without* the distribution axiom, the semantics must be more complex, with a different clause for disjunction required to invalidate the inference of distribution.

It is one thing to use a semantics as a formal device to model a logic. It is another to use a semantics as an *interpretive* device to *apply* a logic. For logics like as the Lambek calculus, the interpretation of the semantics is straightforward. We can take the points to be linguistic units, and the ternary relation to be the relation of composition ($Rxyz$ if and only if x concatenated with y results in z). For the relevant logic **R** and its interpretation of natural language conditionals, more work must be done in identifying what features of reality the formal semantics models. Some of this work is reported in the article on relevant logic in this Encyclopedia.

Bibliography

A comprehensive bibliography on relevant logic was put together by Robert Wolff and can be found in Anderson, Belnap and Dunn 1992. The bibliography in Restall 2000 (see Other Internet Resources) is not as comprehensive as Wolff's, but it does include material up to the last part of the 1990s.

Doing vs. Allowing Harm

Is doing harm worse than allowing harm? If not, there should be no moral objection to active euthanasia in circumstances where passive euthanasia is permissible; and there should be no objection to bombing innocent civilians where doing so will minimize the overall number of deaths in war. There should, however, be an objection—indeed, an outcry—at our failure to prevent the deaths of millions of children in the third world from malnutrition, dehydration, and measles.[1] But is doing harm worse than allowing harm? We might divide approaches to this question into two broad kinds: those that attempt to answer it using examples without saying anything about the nature of the distinction. (Following Shelly Kagan, I'll call this approach 'the contrast strategy.') And those that analyze the distinction in depth and try to show that its underlying nature dictates an answer to the moral question.

---

1. The Contrast Strategy

James Rachels provides a classic example of the first approach.[2] He offers us a pair of cases—in one, Smith drowns his young cousin in the bathtub; in the other, Jones plans to drown his young cousin, but finds the boy already unconscious under water and refrains from saving him. The two cases are exactly alike except that the first is a killing and the second a letting die. Rachels invites us to agree that Smith's behavior is no worse than Jones's. He then concludes that killing per se is no worse than letting die per

se, and that if typical killings are worse than typical lettings die that must be because of other factors.

Although Rachels seems correct about Smith and Jones, the inference from these cases to the moral equivalence of killing and letting die in general (where other things are equal) has been challenged. Shelly Kagan argues that it assumes that "if a factor has genuine moral relevance, then for any pair of cases, where the given factor varies while others are held constant, the cases in that pair will differ in moral status."[3] He claims, moreover, that this assumption assumes the Additive Assumption, the view that "the status of the act is the net balance or sum which is the result of adding up the separate positive and negative effects of the individual factors."[4] He raises several objections to the Additive Assumption. Firstly, one might describe a pair of cases that are exactly alike except that one is a killing and the other a letting die, where the first intuitively seems far worse than the second. If this pair of cases is as good as Rachels' pair, then either the inference is valid in both cases—to prove the contradiction that killing is both worse and not worse than letting die—or it is invalid in both cases. Secondly, one might raise the rhetorical question: why addition—rather than, say, multiplication or some other function?

Instead of using the contrast strategy, let's try to figure out the nature of the distinction between killing and letting die and, more generally, between doing and allowing harm. In both doing and allowing, an agent is responsible for or relevant to a bad upshot—such as a death or injury—in the sense that she could have prevented it. The contrast is most naturally picked out by the terms 'doing' and 'allowing', or 'making' and 'allowing', but since these have vagaries and awkwardnesses in practice, I shall use the terms "positively relevant to an upshot" and "negatively relevant to an upshot" for cases of "doing" and "allowing", respectively.[5]

2. Distinguishing Distinctions

Suppose some upshot occurs and would not have occurred if the agent had behaved in some different way. The question of whether the agent is positively or negatively relevant to the upshot is often conflated with or distorted by questions that should be kept distinct from it, like the questions of (i) whether the agent intended the upshot, (ii) whether she could easily have prevented the upshot, (iii) whether she guaranteed the upshot or merely made it probable, and even (iv) whether the agent's behavior was morally objectionable. It can easily be seen that these do not coincide with the distinction between doing and allowing.

> (i) Consider the distinction between cases where an agent intends the upshot and cases where she does not. If you drive your car into someone's body and she dies as a result, you undoubtedly killed her, even if you did not intend her death. Conversely, someone may intentionally allow a child to drown in order to inherit his fortune.
>
> (ii) It tends to be easier to avoid killing than to avoid letting die, but this is only a tendency. Sometimes saving is easier than not killing. It is easy to throw a life preserver,

and it may be difficult to refrain from killing someone who is threatening one or who has treated one appallingly. There are even cases where it is physically difficult to avoid killing&3151;as for example, where one has to hold tight to a tree to prevent one's (light) vehicle whose brakes have failed from running into a pedestrian.

(iii) Sometimes the terms ‘making’ and ‘allowing’ are used to suggest the difference between making certain and making possible or probable. For example, in discussions of the problem of evil, people sometimes say, “Well, God didn't actually make the murder occur. He just allowed it to occur.” This is best understood, I believe, as a distinction between raising the probability of murder to 1 from something less than 1, on the one hand, and raising the probability of murder from 0 to something higher but still less than 1. This is a morally significant distinction but it is not the distinction between doing and allowing. An agent can kill without guaranteeing death. For example, by adding small quantities of poison to her victim's meals she may bring about the death, even though there was a 20% chance that the poison would not kill her. On the other hand, an agent might guarantee the demise of a plant by failing to water it in a situation where she is the only one who can do so.

(iv) Finally, the distinction between killing and letting die is sometimes thought to have, as part of its conceptual content, a moral element. This thought is rarely made explicit, but the way people are inclined to classify cases suggests that they are guided by it. There are two main difficulties with this way of drawing the line. Firstly, if it is true by definition that killing is worse than letting die, then the question of whether killing is worse than letting die is settled in a trivial, circular, uninteresting way. Secondly, there are obvious counterexamples to this crude account—morally appalling cases of letting die—failing to feed one's children—and morally acceptable cases of killing—We have no hesitation talking of killing in self-defense. Let's turn to some more plausible candidates. In what follows I discuss a series of accounts of the distinction, and where appropriate, the moral significance or insignificance of each account.

3. Causing and Not Causing Not to Occur

One natural suggestion is that the agent who is positively relevant to the upshot causes it to occur; whereas the agent who is negatively relevant to the upshot doesn't cause it, but simply fails to prevent it where she could have done so.[6] This suggestion has immediate moral implications. It seems true by definition (almost) that you can be causally responsible only for upshots that you cause. And it is arguably true that you can be morally responsible only for what you are causally responsible for. So, if you cause a bad state of affairs, you've probably done wrong; whereas if you don't cause a bad state of affairs, you haven't. In choosing between killing and letting die, you are choosing between doing wrong and not doing wrong. The question of what you ought to do is then tautologously easy.

This argument begins to get into trouble when we reflect on the fact that we are often responsible for

upshots we allow: the death of the houseplants or the child's illiteracy. When we notice that, in these cases, the plants die or the child remains uneducated because of some failure on the agent's part, it becomes clear that the agent does, in some sense, cause the upshots. Moreover, most widely accepted contemporary accounts of causation imply that some event or fact involving these agents causes the deaths or illiteracy. For example, the counterfactual account of causation—according to which (very roughly) event *E* causes *F* if and only if had *E* not occurred *F* would not have occurred either—implies that it was the agent's failure to water the plants that caused the deaths.[7] John Mackie's INUS condition—according to which *E* causes *F* if and only if *E* is a(n insufficient but) necessary part of a(n unnecessary but)sufficient condition for *F*—implies that the fact that the agent failed to water the plants causes the plants to die.[8]

4. Counterfactual Accounts

We are concerned then with a contrast between two ways the behavior of agents causes upshots. One suggestion is to say that when the agent is positively relevant to the upshot, the upshot would not have occurred if she had been absent from the scene.[9] Suppose, for example, the victim dies because I push his head under water. He wouldn't have died if I had been absent. On the other hand, suppose he is in deep water and cannot swim and I don't save him. He would have drowned anyway if I had been absent. In these two cases, the counterfactual account draws the line in the intuitively correct way.

This account is sometimes used to support the claim that doing harm is worse than allowing harm, on the grounds that, on this account, allowing harm is simply a matter of letting nature take its course, which, other things being equal, is good, or at least permissible. There are two or three quick objections to this argument. Firstly, it assumes that acting (such as killing or saving lives) is a matter of interfering with the course of nature—in other words, that human action is somehow outside of the course of nature. This is extremely controversial. Secondly, even if human action is outside the course of nature, if the agent is faced with a choice between killing one and allowing two to die at the hand of some other agent, this argument would favor neither option since neither involves letting nature take its course. But, as traditionally understood and used, the Doctrine of Doing and Allowing is supposed to favor letting die in this case just as much as in others. Thirdly, interfering in the course of nature is sometimes obviously the better course of action—to stop the bleeding, restart the heart, and so on.

A different way the counterfactual account can be used to support the claim that doing harm is worse than allowing harm is this: if something bad happens when you are not present (or, especially, if you had never existed) then you aren't responsible for it. If we turn our attention to another world where you are present, but which is otherwise exactly like the first, it seems that your presence makes no difference empirically and, hence, should make no difference morally. This superficially compelling argument seems to prove too much—politicians' careers have hung on the question of whether they were in the room at the time the conspiracy was being hatched. Moreover, suppose an SS officer, Franz, tortures someone to death. But this is standard practice in the Gestapo. If Franz had stayed home with a sore throat, or if Franz had never existed, his pal Hans would have done the torturing, in the same way, at the same time Franz did. If the counterfactual account is correct, then Franz is negatively relevant to the

victim's death by torture. That is, Franz merely allowed the death to occur. This case also creates problems for the idea that killing is worse than letting die, since the fact that Hans was waiting in the wings in no way diminishes Franz's wrongdoing in this case.[10] So, this way of drawing the distinction is problematic, and this argument for the moral significance of the distinction is flawed.

Alan Donagan suggests a similar account of the distinction.[11] To determine whether the agent is positively or negatively relevant to an upshot, we should consider what would have happened if the agent had not acted at the relevant moment, or what would have happened if the agent had 'abstained from intervening in the course of nature'. It isn't entirely clear what we are supposed to imagine when we imagine this but perhaps it's that the agent is asleep or in a trance or in some other way not exercising her agency. Now—with respect to some behavior that led to some upshot, we might ask: would that upshot have occurred if the agent had abstained from intervening in the course of nature? If it would have, the agent allowed the upshot. If it would not have, then she did it (her relevance to the upshot is positive).

The Hans/Franz example can be revised to work against Donagan's version, but here's an additional counterexample. Suppose a man is lying asleep on the ground. He is awoken by a crash and notices a large rock rolling down the hill towards him. He can easily move out of its way, but realizes that if he does so the rock will gain momentum and kill a group of small deaf children further down the hill. He tenses his muscles, fights his desire to run away and stands his ground. The rock hits and seriously injures him. But he stops it. And he saves the children. Donagan's account, however, seems to imply that he merely allows the rock to stop, since, had he remained asleep, the rock would have struck and been stopped by his body.[12]

5. Action, Inaction and Positive and Negative Rights

Warren Quinn offers an account of the distinction—guided he admits by the conviction that doing harm is worse than allowing harm[13] —according to which an agent is positively relevant to a harmful upshot when his most direct contribution to the harm is an action, whether his own or that of some object.[14] His relevance is negative when his most direct contribution is an inaction, a failure to prevent the harm. An agent's most direct contribution to a harmful upshot of his agency is the contribution that most directly explains the harm. And one contribution explains harm more directly than another if the explanatory value of the second is exhausted in the way it explains the first.

The key difference here is between cases where the agent produces the result by an action and cases where she produces it by an inaction—pushing the head under water or refraining from throwing a life preserver. There's an extra complication here, however. Sometimes, Quinn says, your relevance to a death can be positive, you can kill, in other words, even though you don't act. This happens, for example, when you are on a train headed towards some drowning victims you wish to save when you notice someone tied to the tracks ahead of you. You can stop the train but you choose not to in order to reach your destination. Quinn believes that you kill in this case, because the train acts as your agent, taking you

where you want to go, and crushing the person tied to the tracks in the process. On the other hand, if you had chosen not to stop the train for some other reason but you would have not minded had someone else stopped the train, then your failure to stop the train would not have constituted a killing.

What are the moral implications of this way of drawing the line? Following Philippa Foot, Quinn believes that the key here is the distinction between negative and positive rights.[15] Positive relevance to harm involves the violation of negative rights; negative relevance to harm involves the violation of positive rights. Since negative rights are more stringent than positive rights, it is worse to be positively relevant to harm than to be negatively relevant to harm (*ceteris paribus*). But why should we think negative rights more stringent. Here's Quinn:

> [i]n such a morality [neutral vis á vis killing and letting die] the person trapped on the road has a moral say about whether his body may be destroyed only if what he stands to lose is greater than what others stand to gain. But then surely he has no real say at all. For, in cases where his loss would be greater than the gain to others, the fact that he could not be killed would be sufficiently explained not by his authority in the matter but simply by the balance of overall costs. And if this is how it is in general—if we may rightly injure or kill him whenever others stand to gain more than he stands to lose—then surely his body (one might say his person) is not in any interesting moral sense his. It seems rather to belong to the human community, to be dealt with according to its best overall interest…. Whether we are speaking of ownership or more fundamental forms of possession, something is, morally speaking, his only if his say over what may be done to it (and thereby to him) can override the greater needs of others.[16]

To say that one has a negative right against being harmed is to say that it is (at least, prima facie) wrong to harm one unless one wishes to be harmed. It is crucial that we add the phrase "unless one wishes to be harmed", since without it, the precedence of negative rights wouldn't give the victim any special say about his own body, because it would be just as wrong to harm him even if he asked to be harmed, and it would be wrong for him to harm himself. So, the crucial thing is that the victim has some sort of a say about what happens to himself(i.e., others are morally bound to respect his wishes with respect to his body to a certain extent). Quinn's claim is that if there is no extent to which someone's wishes with respect to his body, etc. are to be respected, then we've completely done away with the idea of ownership of one's body, etc.

One person's wishes about what happens to her body do often clash with someone else's wishes about what happen to his. For example, Susie wishes to marry Paul, but Paul doesn't wish to marry Susie. Morality obviously cannot give all such wishes precedence. So, the suggestion goes, let's give some subset of them precedence. For example, let's give negative wishes precedence. Why, what's so special about negative wishes? "Well, nothing," the answer seems to go. "But unless we give some wishes precedence, there will be no domain in which the victim's personal preference takes precedence; and in that case, there will be no sense in which the agent is lord in that domain. In other words, without some such precedence there will be no ownership of one's body or mind, etc." Quinn argues that we cannot

give positive rights precedence over negative rights without incoherence.[17] And, hence, he concludes that we must give negative rights precedence over positive rights.

But there are other ways to divide up rights than the division into positive and negative rights. We might divide them into the rights of children and the rights of adults, rights concerning the upper half of the body and rights concerning the lower half, etc. and then give precedence to one set over the other whenever they come into conflict. These seem arbitrary and wasteful, but their rationale seems no worse than Quinn's.

Quinn's is a funny sort of defense of negative rights. Unless I'm missing something, it doesn't pick out any special feature of negative rights that makes them specially worth respecting.

6. The ‘Most of the Things He Could have Done’ Account

Like Quinn, Jonathan Bennett thinks that the fundamental distinction between doing and allowing is between cases where the upshot occurs because of one's action and cases where the upshot occurs because of one's inaction—although he prefers to replace “action/inaction” talk with “positive/negative fact” talk.[18] When Bennett discusses the contrast between positive and negative relevance to harm, he is attempting to capture a deep, philosophically interesting distinction that underlies our talk of ‘doing and allowing’ ‘making and letting’,‘killing and letting die’. He acknowledges that the correspondence between his distinction and the distinctions we make in everyday life and language may be inexact. He says that my behavior is negatively relevant to an upshot if a negative fact about my behavior is the least informative fact that suffices to complete a causal explanation of it; whereas my behavior is positively relevant to that upshot if a positive fact about my behavior is the least informative fact about my conduct that suffices to complete a causal explanation of it. For example, if I jog while you drown, your drowning could be explained by the fact that I jogged, but it could also be explained by the less informative fact that I did not pull you out.

In a nutshell, on Bennett's view, an agent's relevance to an upshot is positive if most of the ways she could have behaved at the time would not have led to the upshot; otherwise, it is negative.[19] For example, suppose I douse a slug with salt and it dies as a result. My relevance to its demise is positive, since most of the ways I could have behaved would not have led to the death. On the other hand, if it dies because I fail to move it from the path of a car, then most of the ways I could have behaved at the time would have led to its death, so my relevance to the death is negative.

On this account, doing harm is no worse than allowing harm. If some upshot obtains because of the way you behaved, then the fact that there were many ways (rather than only a few) you could have behaved which would also have had that result is morally insignificant. This conclusion is surprising, even shocking. Bennett's account, however, can explain why we tend to think of killing as worse than letting die. He claims, quite plausibly, that it is morally worse to be causally relevant to a bad upshot one could

easily have avoided than a similarly bad upshot one could have avoided only with great difficulty. If most of the ways one could have behaved would have led to an upshot, then it was probably somewhat difficult or onerous to avoid the upshot; whereas if most of the ways one could have behaved would not have led to an upshot, then it was probably fairly easy to avoid the upshot. This correlation is not inevitable, however. It is easy to call 911, and can be difficult to refrain from killing a child at the bottom of a well if your only alternative is to continue hanging from a rope above her.

In spite of its virtues, Bennett's account faces some formidable difficulties. It has often been attacked with counterexamples like the following:

> Raccoon: Returning to the campsite after fetching water, I notice a raccoon eating my food. Hiding behind some trees downwind of him, I know that if I make a noise he will run away. I notice a large bell near me, but decide against using it, allowing the raccoon to eat my food.

Bennett's account, of course, says just that. But let's change the story slightly. Suppose now that I am closely surrounded by bells. If I move at all, I will make a sound loud enough to scare off the raccoon. Again, I don't move and he eats on undisturbed. It seems that I still allow the food to be eaten. The addition of more bells doesn't change this.

Some philosophers argue that such examples refute Bennett's account.[20] Their diagnosis of the difficulty goes like this: "What's important here is that the agent is immobile throughout. Immobility is incompatible with positive relevance to an upshot. Nifty slogan: 'You cannot do anything by doing nothing.' Bennett's account wrongly implies that immobility is compatible with positive relevance to an upshot."

But immobility is not necessarily incompatible with positive relevance to an upshot. Consider the case I described earlier of the agent who was positively relevant to the rock's stopping and the children's being unscathed by standing his ground, precisely by not moving. Here's another case. After a mild earthquake the agent finds herself sitting on a child's chest. Unless she moves soon, the child's lungs will be crushed. She stays put. The child dies. It is not implausible to say that the agent killed the child, although she was completely immobile throughout the relevant time period.[21] These cases make it clear that immobility doesn't rule out positive relevance. But if it is not my immobility that explains the fact that I am negatively relevant to the raccoon's consuming my food, what is it?

Before answering this question, let's consider another difficult case for Bennett's account, Sassan: An assassin, A. Sassan, is preparing to assassinate Victor by shooting him. A second assassin, Baxter, is waiting across the street watching Sassan to ensure his success. If Sassan shows any signs of hesitation, Baxter will shoot Victor himself. Suppose Sassan knows about Baxter and his intentions and also knows that he can turn his gun on Baxter instead of on Victor if he so chooses. Although this thought crosses his mind, he quickly suppresses it, since he is committed to Victor's annihilation. He shoots Victor and Victor dies instantly. Most of the ways he could have behaved would have led to the shooting and death

of Victor (either by himself or by Baxter). By Bennett's account, Sassan's relevance to the fact that Victor is shot and killed is negative. This means that Sassan doesn't kill Victor, but merely lets him die. Hold on! I just said that Sassan shot Victor. He pulled the trigger. The gun fired. A bullet flew out of the barrel and entered Victor's body. Victor died from the bullet wound. A clearer case of killing is impossible to find. Bennett might repeat the point that positive relevance to a death is not exactly the same as killing. Nevertheless, insofar as we have any pre-theoretical grip on (and interest in) the concept of positive relevance to a death, Sassan's relevance to Victor's death must strike us as positive rather than negative.[22] And yet Bennett's account implies that it is negative.

Someone sympathetic with Bennett's account may attempt to demonstrate that that account does accommodate our intuitions on this score by claiming that it implies that Sassan's behavior is positively relevant to the actual death that Victor died, since if Baxter had killed him, he would have died a different death. This response is not consistent with Bennett's approach, however, since it the phrases ‘the actual death’ and ‘a different death’ seem to be referring to events rather than facts. And Bennett is clearly concerned with relevance to facts not events.

Bennett himself has pointed out that the upshot that concerns us is not the fact that Victor died (no-one could prevent that) but the fact that Victor died at T (or perhaps, the fact that Victor died no later than T).[23] He suggested that perhaps Sassan is positively relevant to that, since most of the ways he could have behaved would have resulted in Victor's dying later than T. But we could, with minimal artifice, ensure that Baxter is disposed to kill Victor at exactly T if Sassan does not. For example, we could imagine that there is only a fraction of a second when Victor is vulnerable to a bullet and that Baxter is located closer to him (or has a faster acting gun) so that there is a moment T_2 such that if Sassan does not shoot at T_2, he will not succeed in killing Victor, but such that Baxter still has a chance to get a shot off at T_1 with the result that Victor will die at T.

Perhaps someone may try to argue that Sassan is positively relevant to something—the fact that Victor is killed with this bullet rather than that, or more simply the fact that Victor is killed by him rather than by Baxter. The latter suggestion will not do, since it begs the question. Bennett cannot assume that his account implies that Sassan kills Victor, since that is the very claim at issue. As to the suggestion that Sassan is positively relevant to Victor's being killed with this bullet rather than that, surely we could modify the story in such a way that if Sassan does not pull the trigger, Baxter can push a switch that will guarantee that the gun fires.

So it seems that Bennett is committed to the claim that Sassan is negatively relevant to (the various salient facts concerning) Victor's death, and hence, that Sassan let Victor die. This seems wrong.

7. The Transfer of Energy Account

Why do we think of Sassan's relevance to Victor's death as positive? Surely because Sassan ‘acts on’ him in a way that one does not ‘act on’ a drowning victim if one simply stands by and watches him drown.

Similarly, the woman who crushed the child's chest by pressing on it (while remaining immobile) acted on the child to cause his death. By contrast, in Raccoon, my role in the event of the raccoon's consuming my food was precisely not to act on the raccoon. In cases of ‘acting on’, it seems, physical forces run from the agent to the affected object or patient. This seems to distinguish typical cases of doing from typical cases of allowing harm.

Let's clarify the account. Obviously the agent need not act on the patient directly—it is enough that physical forces run from one to the other, however indirectly. Moreover, it cannot be sufficient for positive relevance to an upshot that physical forces run from the agent to the victim or patient at the appropriate time. The agent may have acted on the patient but done so to produce some other effect. For example, instead of drowning him or pulling him out, she throws him a rose. A passenger on a runaway trolley doesn't seem to kill the victim of that trolley in spite of the fact that his weight adds to the momentum of the trolley and, hence, there is a transfer of energy between the two. We should add that the way in which she acts on him must explain the upshot. In the case just described, because her throwing him a rose doesn't explain his death by drowning, she doesn't count as positively relevant to his death.[24]

A puzzle remains. What about cases where the agent removes a safety net from beneath a falling victim, unplugs a respirator, kicks a rock out of the path of the runaway vehicle, and other similar cases? No physical forces run from the agent to the victim. So, by the account under discussion, they are cases of negative relevance, and yet many of them, at least by many people, are confidently judged to be cases of positive relevance. Of course, such cases are by their nature troublesome and controversial. Unlike Sassan and Raccoon, these may be cases of “spoils to the victor”—cases we should classify in whatever way the otherwise best theory does.[25] The “acting on” account could fairly easily be adapted so that it treated such “safety net” cases as cases of positive relevance. Instead of insisting on one or another version of that account, let me outline three versions of it.

A. According to the first, safety net cases are cases of negative relevance because, although the agent acts on the net, the net does not act on the victim.
B. According to the second, they are cases of positive relevance because the agent acts on the net (physical forces run from the agent to the net) and the position of the net is a necessary part of the causal explanation of the victim's death. More generally: The agent is positively relevant to an upshot *U* if the agent acts on *X* to produce feature *F* in *X* and *X*s having *F* is a necessary part of the causal story leading to *U*.[26]
C. According to the third version, it is not a clear case of positive relevance because although she acts on the net, the net does not act on the victim, but nor is it a clear case of negative relevance, because the relevance of her behavior to the upshot is not in terms of her failure to act on something. It is a borderline case.

I submit that this distinction between cases where the agent acts on the victim and cases where she does not is at least one strand in the complex tangle underlying our commonsense distinction between doing and allowing. If that is right, what are the moral implications? Not clear, I think, but this distinction does

help explain our tendency to be more upset when we kill than when we let die. When physical forces run from the agent to the victim (even where the agent is uncontroversially innocent) there tends to be something like a jolt—as one experiences the death of which one is a causal factor. Consider a case where the victim jumps or is thrown in front of the agent's car. Although there is no question of the agent's guilt in this case, the event must feel more distressing to her than would a case where she is aware of a death that she cannot prevent.[27]

8. More on 'Safety Net' Cases

Jeff McMahan puts "safety net cases" front and center of his own account of the distinction, arguing that some of them qualify as killings and some as lettings die.[28] A number of factors distinguish the killings from the lettings die. "Among these are whether the person who terminates the aid or protection is the person who has provided it, whether the aid or protection is self-sustaining or requires more of the agent, and whether the aid or protection is operative or as yet inoperative."[29] Here are three cases he discusses:

- (Burning Building 1): A person trapped atop a high burning building leaps off. Seeing this, a firefighter quickly stations a self-standing net underneath. But he then immediately notices that two other persons have jumped from a window several yards away. He therefore repositions the net so that it catches the two. The first jumper then hits the ground and dies.
- (Burning Building 2): Just like (Burning Building 1) except that it is a second firefighter who repositions the net.
- (Burning Building 3): Just like (Burning Building 2) except that the second firefighter moves the safety net out of a malicious desire to kill.

Convinced that (Burning Building 2) is importantly like (Burning Building 1), McMahan points out that sometimes one agent can act on behalf of another, or they can act as a team (e.g., of firefighters) so that whether it is the first or the second firefighter doesn't matter, since they are acting in a capacity that is "role-based". In (Burning Building 3), however, where the second firefighter is motivated by malice against the victim, he is acting on his own and kills the victim.

The messy, somewhat ad hoc nature of McMahan's way of drawing the line is clearly a strike against it, as is the fact that it is clearly motivated by a desire to accommodate the moral intuition that killing is worse than letting die. If, however, some or all of the factors that McMahan lists as affecting the question of whether a case is one of killing or letting die can be seen to follow from some simpler, deeper account of the distinction, so much the better for that account and for McMahan's judgments about cases. Here's a way this might be done. It is somewhat arbitrary how we count actions—whether my typing the word 'word' involves four actions or just one, for example. Similarly, it is arbitrary whether the behavior of first writing a (potentially life-saving) check and then tearing it up count as a single action or as two. The simple action of tearing it up might be classified as a killing, whereas the complex 'act' of writing it and tearing it up might seem equivalent to the non-act of never writing it, and, hence, count as letting die. In asking whether the agent killed or let die in such a case, we may sometimes focus on the second (simple)

act and sometimes on the complex act. Whether the two are performed by the same person, the time between the two, whether the first was self-sustaining, etc. all affect our choice here. It seems that Bennett's or the counterfactual account may, with minimal artifice, be modified so that most of the cases that McMahan wants to classify as lettings die are so classified. For example, we might consider what would have happened if the agent had not been present (during the entire period—including the time of writing the check and the time of tearing it up.) or we might consider whether most of the ways the agent could have behaved throughout the entire period would have had the result that upshot obtained.

McMahan's suggestion that the firefighter kills if he acts with a malicious intention, whereas he lets die if he acts with a good intention seems wrong, however. Whatever else we think about doing and allowing, we should be able to distinguish them without reference to internal mental states of the agent.

9. Conclusion

This discussion suggests, I think, that “the distinction between doing and allowing" does not refer uniquely. More likely, it refers indefinitely to a tissue of largely overlapping distinctions—such as Bennett's, the counterfactual account, and the transfer of energy account, in addition to, (if we like) complex, conjunctive distinctions like Quinn's or McMahan's. The fact that each account faces counterexamples may not show that each is incorrect, but simply that none is the unique distinction. In that case, it seems that the sensible approach is to acknowledge this variety of distinctions, and to ask with respect to each, whether it is morally significant.[30] I believe my discussion has shown that there is no decisive reason to say that any of these distinctions is morally significant, as long, that is, as we remember that intention plays no part in the distinction between doing and allowing harm. I have no doubt that the intention with which an agent acts can make a difference to the moral status of her act. (Exactly how is a big question—for another paper.) The claim that doing harm is no worse than allowing harm flies in the face of powerful intuitions to the contrary. I believe that these intuitions can be partially explained away by pointing to other morally significant distinctions (distinctions concerning intentions, difficulty or ease of avoiding the harm, etc) that often coincide with the distinction between doing and allowing harm. A residue remains, however, and we seem faced with a conflict between theory and intuitions about cases.

Stanford Encyclopedia of Philosophy
Notes to Doing vs. Allowing Harm

Notes

1. This issue is relevant also to the debate over abortion, the debate over capital punishment, and the more theoretical debate over consequentialism. See Scheffler, Smart and Williams.

2. James Rachels, “Active and Passive Euthanasia,”. See also Michael Tooley, “Abortion and Infanticide,” *Philosophy and Public Affairs* 2 1972, Peter Singer, *Practical Ethics*,1979 and Peter Unger, *Living High and Letting Die*.

3. “The Additive Fallacy”.

4. *Ibid*., 259. See Heidi Malm (1992) for a response to Kagan.

5. We talk about allowing the tree to fall, but we do not talk about “doing the tree fall”. We do of course talk about “making the tree fall” and “causing the tree to fall,” but I am reluctant to use these terms, because they suggest that allowing the tree to fall is not a way of causing it to fall, and, as I shall argue below, this is wrong.

6. See, for example, Daniel Callahan, 1989.

7. This idea, which has its roots in Hume's writings, is developed in Lewis, 1986. Note that the definition I mention in the text represents the gut idea of the counterfactual account of causation. Subsequent versions are much more complicated, but they all imply that letting die is a kind of causing.

8. See Mackie, 1974. According to “transference” accounts of causation, causation consists in the transfer of energy or momentum from one object to another at the point of contact between the objects. Such accounts would indeed imply that allowing was not causing. See J. Aronsen, 1971 . But it seems then that a different premise in the argument for the moral insignificance of the distinction would be in trouble. The thought that one cannot be morally responsible for what one is not causally responsible for now seems dubious. It seemed correct, before, I conjecture, because, on the counterfactual accounts, it is very close to the principle that ‘ought’ implies ‘can’. If the transference account of causation is correct, then lack of causal responsibility does not imply inability to make a difference.

9. Or “ if the agent had never existed.” See Shelly Kagan, 1989, p. 94 ff for this version.

10. It might be objected that, had Franz been absent, the death would not have occurred, because the victim would have died a different death, since he would have been killed by Hans rather than by Franz. It seems to me that this response fails, since it is simply asserting the very point at issue: that the counterfactual account implies that Franz killed.

11. See Donagan, 1977.

12. See Christian Munthe, 1999, for an interesting attack on the claim that the counterfactual distinction is morally significant. Munthe argues that if true, this claim would violate the rule that ‘ought’ implies ‘can’.

13. See Warren Quinn, “Actions, Intentions, and Consequences: The Doctrine of Doing and Allowing.”.

14. Quinn uses the expression, “harmful positive agency” for doing harm and “harmful negative agency” for allowing harm. This idea can be traced back at least to Anscombe and Davidson (see Anscombe, 1958 and Davidson, 1980.)

15. See Foot, 1985. Note that Quinn's argument for the moral significance of the distinction doesn't seem to hang on his account of the distinction.

16. *Ibid*., p. 156.

17. See Strudler and Wasserman for an interesting critique of this point.

18. Bennett has developed and defended these ideas in a series of articles and a book. See Bennett, 1967, 1981, 1993, 1995.

19. This nutshell leaves out much important detail. See the original.

20. For example, Daniel Dinello (1971). Quinn makes a similar point in “Actions, Intentions, and Consequences.”

21. If you feel that whether this counts as a killing depends on other factors such as what the agent knows or desires, add whatever features will make it seem most favorable to me. My point is simply that sometimes an agent can kill while remaining completely immobile. Robin Dillon helped me to see this point. Bennett offers several other reasons for thinking that the immobility objection is not decisive against him. See p. 98 ff of *The Act Itself*.

22. This objection was suggested to me by remarks of Paul Wagoner. Note that Sassan bears obvious resemblances to Harry Frankfurt's famous counterexample to the Principle of Alternative Possibilities.

See Frankfurt, 1969. It is importantly different from that example, however.

23. In correspondence.

24. I am indebted to John Hawthorne for with the ideas of this paragraph. Does every case of this sort have a victim? It is arguable that every upshot consists in a state or event occurring in some object or objects. Let that object or objects be the 'victim' with which, directly or indirectly, the agent interacts.

25. I was surprised to learn—from Jonathan Schaffer—that firing a gun is a safety net case—that most triggers work by removing a barrier and "allowing" pent-up energy to release the bullet. This example suggests that we had better put safety net cases on the positive side of the line.

26. I need to insist that the agent is not identical with *X*. Without this qualification, some very standard cases of allowing would count as positive relevance, since the agent might be said to act on herself to prevent herself from saving the victim. I'm not sure that it even makes sense to talk of an agent acting on herself, or of forces running from her to herself, but if it does, let us exclude such cases.

27. Bernard Williams discusses a case like this. See his 1973, pp. 98-99.

28. In "Killing, Letting Die and Withdrawing Aid". See Tracy Isaacs (1995) for a powerful critique of McMahan.

29. *Ibid*., (in Norcross and Steinbock) p. 396.

30. Matthew Hanser argues that we should recognize a third category here: preventing someone from being saved. I think this treatment of "safety net" cases can be seen as confirming my point about the tissue of overlapping distinctions. Clear cases of killing fall on the positive side of all of the candidate distinctions, clear cases of allowing death fall on the negative side of all the distinctions; indeterminate cases fall on one side of one distinction and on the other side of another distinction. Treating these as a third category is just another way of making the same point. See Hanser, 1999.

Privacy

The term “privacy” is used frequently in ordinary language as well as in philosophical, political and legal discussions, yet there is no single definition or analysis or meaning of the term. The concept of privacy has broad historical roots in sociological and anthropological discussions about how extensively it is valued and preserved in various cultures. Moreover, the concept has historical origins in well known philosophical discussions, most notably Aristotle’s distinction between the public sphere of political activity and the private sphere associated with family and domestic life. Yet historical use of the term is not uniform, and there remains confusion over the meaning, value and scope of the concept of privacy.

Early treatises on privacy appeared with the development of privacy protection in American law from the 1890’s onward, and privacy protection was justified largely on moral grounds. This literature helps distinguish *descriptive* accounts of privacy, describing what is in fact protected as private, from *normative* accounts of privacy defending its value and the extent to which it should be protected. In these discussions some treat privacy as an *interest* with moral value, while others refer to it as a moral or legal *right* that ought to be protected by society or the law. Clearly one can be insensitive to another’s privacy interests without violating any right to privacy, if there is one.

There are several skeptical and critical accounts of privacy. According to one well known argument there is no right to privacy and there is nothing special about privacy, because any interest protected as private can be equally well explained and protected by other interests or rights, most notably rights to property and bodily security (Thomson, 1975). Other critiques argue that privacy interests are not distinctive because the personal interests they protect are economically inefficient (Posner, 1981) or that they are not grounded in any adequate legal doctrine (Bork, 1990). Finally, there is the feminist critique of privacy, that granting special status to privacy is detrimental to women and others because it is used as a shield to dominate and control them, silence them, and cover up abuse (MacKinnon, 1989).

Nevertheless, most theorists take the view that privacy is a meaningful and valuable concept. Philosophical debates concerning definitions of privacy became prominent in the second half of the twentieth century, and are deeply affected by the development of privacy protection in the law. Some defend privacy as focusing on control over information about oneself (Parent, 1983), while others defend it as a broader concept required for human dignity (Bloustein, 1964), or crucial for intimacy (Gerstein, 1978; Inness, 1992). Other commentators defend privacy as necessary for the development of varied and meaningful interpersonal relationships (Fried, 1970, Rachels, 1975), or as the value that accords us the ability to control the access others have to us (Gavison, 1980; Allen, 1988), or as a set of norms necessary not only to control access but also to enhance personal expression and choice (Schoeman,

1992), or some combination of these (DeCew, 1997). Discussion of the concept is complicated by the fact that privacy appears to be something we value to provide a sphere within which we can be free from interference by others, and yet it also appears to function negatively, as the cloak under which one can hide domination, degradation, or physical harm to women and others.

This essay will discuss all of these topics, namely, (1) the historical roots of the concept of privacy, including the development of privacy protection in tort and constitutional law, and the philosophical responses that privacy is merely reducible to other interests or is a coherent concept with fundamental value, (2) the critiques of privacy as a right, (3) the wide array of philosophical definitions or defenses of privacy as a concept, providing alternative views on the meaning and value of privacy (and whether or not it is culturally relative), as well as (4) the challenges to privacy posed in an age of technological advance. Overall, most writers defend the value of privacy protection despite the difficulties inherent in its definition and its potential use to shield abuse. A contemporary collection of essays on privacy provides strong evidence to support this point (Paul *et al*., 2000). The contributing authors examine various aspects of the right to privacy and its role in moral philosophy, legal theory, and public policy. They also address justifications and foundational arguments for privacy rights.

---

1. History

Aristotle's distinction between the public sphere of politics and political activity, the *polis*, and the private or domestic sphere of the family, the *oikos*, as two distinct spheres of life, is a classic reference to a private domain. The public/private distinction is also sometimes taken to refer to the appropriate realm of governmental authority as opposed to the realm reserved for self-regulation, along the lines described by John Stuart Mill in his essay, *On Liberty*. Furthermore, the distinction arises again in Locke's discussion of property in his *Second Treatise on Government*. In the state of nature all the world's bounty is held in common and is in that sense public. But one possesses oneself and one's own body, and one can also acquire property by mixing one's labor with it, and in these cases it is one's private property. Margaret Mead and other anthropologists have demonstrated the ways various cultures protect privacy through concealment, seclusion or by restricting access to secret ceremonies (Mead, 1949). Alan Westin (1967) has surveyed studies of animals demonstrating that a desire for privacy is not restricted to humans. However, what is termed private in these multiple contexts varies. Privacy can refer to a sphere separate from government, a domain inappropriate for governmental interference, forbidden views and knowledge, solitude, or restricted access, to list just a few.

1.1 Informational Privacy

More systematic written discussion of the concept of privacy is often said to begin with the famous essay by Samuel Warren and Louis Brandeis titled "The Right to Privacy" (Warren and Brandeis, 1890). Citing "political, social, and economic changes" and a recognition of "the right to be let alone" they argued that existing law afforded a way to protect the privacy of the individual, and they sought to explain the nature and extent of that protection. Focusing in large part on the press and publicity allowed by recent inventions such as photography and newspapers, but referring as well to violations in other contexts, they emphasized the invasion of privacy brought about by public dissemination of details relating to a person's private life. Warren and Brandeis felt a variety of existing cases could be protected under a more general right to privacy which would protect the extent to which one's thoughts, sentiments, and emotions could be shared with others. Urging that they were not attempting to protect the items produced, or intellectual property, but rather the peace of mind attained with such protection, they said the right to privacy was based on a principle of "inviolate personality" which was part of a general right of immunity of the person, "the right to one's personality" (Warren and Brandeis 1890, 195, 215). The privacy principle, they believed, was already part of common law and the protection of one's home as one's castle, but new technology made it important to explicitly and separately recognize this protection under the name of privacy. They suggested that limitations of the right could be determined by analogy with the law of slander and libel, and would not prevent publication of information about public officials running for office, for example. Warren and Brandeis thus laid the foundation for a concept of privacy that has come to be known as control over information about oneself.

Although the first cases after the publication of their paper did not recognize a privacy right, soon the public and both state and federal courts were endorsing and expanding the right to privacy. In an attempt

to systematize and more clearly describe and define the new right of privacy being upheld in tort law, William Prosser wrote in 1969 that what had emerged were four different interests in privacy. Not claiming to be providing an exact definition, and admitting that there had been confusion and inconsistencies in the development of privacy protection in the law, Prosser nevertheless described the four “rather definite” privacy rights as follows:

1. Intrusion upon a person’s seclusion or solitude, or into his private affairs.
2. Public disclosure of embarrassing private facts about an individual.
3. Publicity placing one in a false light in the public eye.
4. Appropriation of one’s likeness for the advantage of another (Prosser 1969, 389).

Prosser noted that the intrusion in the first privacy right had expanded beyond physical intrusion, and pointed out that Warren and Brandeis had been concerned primarily with the second privacy right. Nevertheless, Prosser felt that both real abuses and public demand had led to general acceptance of these four types of privacy invasions. On his view, answers to three main questions were at the time as yet unclear: i) whether appearance in public implied forfeiture of privacy, ii) whether facts part of a “public record” could still be private, and iii) whether a significant lapse of time affected the privacy of revelations. Note that Warren and Brandeis were writing their normative views about what they felt should be protected under the rubric of privacy, whereas Prosser was describing what courts had in fact protected in the 70 years following publication of the Warren and Brandeis paper. Thus it is not surprising that their descriptions of privacy differ. Because the Supreme Court has been explicit in ruling that privacy is a central reason for Fourth Amendment protection, privacy as control over information about oneself has come to be viewed by many as also including protection against unwarranted searches, eavesdropping, surveillance, and appropriation and misuses of one’s communications.

1.2 The Constitutional Right to Privacy

In 1965 a quite different right to privacy, independent of informational privacy and the Fourth Amendment, was recognized explicitly by the Supreme Court. It is now commonly called the constitutional right to privacy. The right was first announced in the *Griswold v. Connecticut* (381 U.S. 479) case, which overturned convictions of the Director of Planned Parenthood and a doctor at Yale Medical School for dispersing contraceptive related information, instruction, and medical advice to married persons. The constitutional right to privacy was described by Justice William O. Douglas as protecting a zone of privacy covering the social institution of marriage and the sexual relations of married persons. Despite controversy over Douglas’ opinion, the constitutional privacy right was soon cited to overturn a ban against interracial marriage, to allow individuals to possess obscene matter in their own homes, and to allow distribution of contraceptive devices to individuals, both married and single. The most famous application of this right to privacy was as one justification of abortion rights defended in 1973 in *Roe v. Wade* (410 U.S. 113) and subsequent decisions on abortion. While Douglas vaguely called it a “penumbral” right “emanating” from the Constitution, and the Court has been unable to clearly define the right, it has generally been viewed as a right protecting one’s individual interest in independence in making certain important and personal decisions about one’s family, life and lifestyle.

Which personal decisions have been protected by this privacy right has varied depending on the makeup of the Court. In 1986 in *Bowers v. Hardwick* (478 U.S. 186) privacy was not held to cover a ban on anti-sodomy laws in Georgia, despite the intimate sexual relations involved.

1.3 Reductionism vs. Coherentism

One way of understanding the growing literature on privacy is to view it as divided into two main categories, which we may call *reductionism* and *coherentism*. Reductionists are generally critical of privacy, while coherentists defend the coherent fundamental value of privacy interests. Ferdinand Schoeman (1984) introduced somewhat different terminology which makes it easier to understand this distinction. According to Schoeman, a number of authors have believed

> ...there is something fundamental, integrated, and distinctive about the concerns traditionally grouped together under the rubric of "privacy issues." In opposing this position, some have argued that the cases labeled "privacy issues" are diverse and disparate, and hence are only nominally or superficially connected. Others have argued that when privacy claims are to be defended morally, the justifications must allude ultimately to principles which can be characterized quite independently of any concern with privacy. Consequently, the argument continues, there is nothing morally distinctive about privacy. I shall refer to the position that there is something common to most of the privacy claims as the "coherence thesis." The position that privacy claims are to be defended morally by principles that are distinctive to privacy I shall label the "distinctiveness thesis."
>
> Theorists who deny both the coherence thesis and the distinctiveness thesis argue that in each category of privacy claims there are diverse values at stake of the sort common to many other social issues and that these values exhaust privacy claims. The thrust of this complex position is that we could do quite well if we eliminated all talk of privacy and simply defended our concerns in terms of standard moral and legal categories (Schoeman 1984, 5).

These latter theorists, who reject both Schoeman's coherence thesis and distinctiveness thesis, may be referred to as *reductionists*, for they view what are called privacy concerns as analyzable or reducible to claims of other sorts, such as infliction of emotional distress or property interests. They deny that there is anything useful in considering privacy as a separate concept. They conclude, then, that there is nothing coherent, distinctive or illuminating about privacy interests.

On the other side, more theorists have argued that there is something fundamental and distinctive and coherent about the various claims that have been called privacy interests. On this view, privacy has value as a coherent and fundamental concept, and most individuals recognize it as a useful concept as well. Those who endorse this view may be called *coherentists*. Nevertheless, it is important to recognize that coherentists have quite diverse, and sometimes overlapping, views on what it is that is distinctive about

privacy and what links diverse privacy claims.

2. Critiques of Privacy

2.1 Thomson's Reductionism

Probably the most famous reductionist view of privacy is one from Judith Jarvis Thomson (1975). Noting that there is little agreement on what privacy is, Thomson examines a number of cases that have been thought to be violations of the right to privacy. On closer inspection, however, Thomson believes all those cases can be adequately and equally well explained in terms of violations of property rights or rights over the person, such as a right not to be listened to. Ultimately the right to privacy, on Thomson's view, is merely a cluster of rights. Those rights in the cluster are always overlapped by, and can be fully explained by, property rights or rights to bodily security. The right to privacy, on her view, is "derivative" in the sense that there is no need to find what is common in the cluster of privacy rights. Privacy is derivative in its importance and justification, according to Thomson, as any privacy violation is better understood as the violation of a more basic right. Numerous commentators provide strong arguments against Thomson's critique (Scanlon, 1975; Inness, 1992).

2.2 Posner's Economic Critique

Richard Posner (1981) also presents a critical account of privacy, arguing that the kinds of interests protected under privacy are not distinctive. Moreover, his account is unique because he argues that privacy is protected in ways that are economically inefficient. With respect to information, on Posner's view privacy should only be protected when access to the information would reduce its value (e.g. allowing students access to their letters of recommendation make those letters less reliable and thus less valuable, and hence they should remain confidential or private). Focusing on privacy as control over information about oneself, Posner argues that concealment or selective disclosure of information is usually to mislead or manipulate others, or for private economic gain, and thus protection of individual privacy is less defensible than others have thought because it does not maximize wealth. In sum, Posner defends organizational or corporate privacy as more important than personal privacy, because the former is likely to enhance the economy.

2.3 Bork's View

Another strong critic of privacy is Robert Bork (1990), whose criticism is aimed at the constitutional right to privacy established by the Supreme Court in 1965. Bork views the *Griswold v. Connecticut* decision as an attempt by the Supreme Court to take a side on a social and cultural issue, and as an example of bad constitutional law. Bork's attack is focused on Justice William O. Douglas and his majority opinion in *Griswold*. Bork's major point is that Douglas did not derive the right to privacy from some pre-existing right or from natural law, but merely created a new right to privacy with no foundation in the Constitution or Bill of Rights. Bork is correct that the word "privacy" never appears in those

documents. Douglas had argued, however, that the right to privacy could be seen to be based on guarantees from the First, Third, Fourth, Fifth, and Ninth Amendments. Taken together, the protections afforded by these Amendments showed that a basic zone of privacy was protected for citizens, and that it covered their ability to make personal decisions about their home and family life. In contrast, Bork argues i) that none of the Amendments cited covered the case before the Court, ii) that the Supreme Court never articulated or clarified what the right to privacy was or how far it extended, and he charges iii) that the privacy right merely protected what a majority of justices personally wanted it to cover. In sum, he accuses Douglas and the Court majority of inventing a new right, and thus overstepping their bounds as judges by making new law, not interpreting the law.

Theorists including William Parent (1983) and Judith Thomson (1975) argue that the constitutional right to privacy is not really a privacy right, but is more aptly described as a right to liberty. Other commentators believe, to the contrary, that even if Douglas' opinion is flawed in its defense, using vague language about a penumbral privacy right emanating from the Constitution and its Amendments, there is nevertheless a historically and conceptually coherent notion of privacy, distinct from liberty, carved out by the constitutional privacy cases (Inness, 1992; Schoeman, 1992; Johnson, 1994; DeCew, 1997).

2.4 The Feminist Critique of Privacy

There is no single version of the feminist critique of privacy, yet it can be said in general that many feminists worry about the darker side of privacy, and the use of privacy as a shield to cover up domination, degradation and abuse of women and others. If distinguishing public and private realms leaves the private domain free from any scrutiny, then these feminists such as Catharine MacKinnon (1989) are correct that privacy can be dangerous for women when it is used to cover up repression and physical harm to them by perpetuating the subjection of women in the domestic sphere and encouraging nonintervention by the state. Jean Bethke Elshtain (1981, 1995) and others suggest that it appears feminists such as MacKinnon are for this reason rejecting the public/private split, and are, moreover, recommending that feminists and others jettison or abandon privacy altogether. But, Elshtain points out, this alternative seems too extreme.

A more reasonable view, according to Anita Allen (1988), is to recognize that while privacy can be a shield for abuse, it is unacceptable to reject privacy completely based on harm done in private. A total rejection of privacy makes everything public, and leaves the domestic sphere open to complete scrutiny and intrusion by the state. Yet women surely have an interest in privacy that can protect them from state imposed sterilization programs or government imposed drug tests for pregnant women mandating results sent to police, for instance, and that can provide reasonable regulations such as granting rights against marital rape. Thus collapsing the public/private dichotomy into a single public realm is inadequate. What puzzles feminists is how to make sense of an important and valuable notion of privacy that provides them a realm free from scrutiny and intervention by the state, without reverting to the traditional public/private dichotomy that has in the past relegated women to the private and domestic sphere where they are victims of abuse and subjection. The challenge is to find a way for the state to take very seriously the domestic abuse that used to be allowed in the name of privacy, while also preventing the state from

insinuating itself into all the most intimate parts of women's lives. This means drawing new boundaries for justified state intervention and thus understanding the public/private distinction in new ways.

3. Views on the Meaning and Value of Privacy

3.1 Privacy and Control over Information

Narrow views of privacy focusing on control over information about oneself that were defended by Warren and Brandeis and by William Prosser are also endorsed by more recent commentators including Fried (1970) and Parent (1983). In addition, Alan Westin describes privacy as the ability to determine for ourselves when, how, and to what extent information about us is communicated to others (Westin, 1967). Perhaps the best example of a contemporary defense of this view is put forth by William Parent. Parent explains that he proposes to defend a view of privacy that is consistent with ordinary language and does not overlap or confuse the basic meanings of other fundamental terms. He defines privacy as the condition of not having undocumented personal information known or possessed by others. Parent stresses that he is defining the condition of privacy, as a moral value for people who prize individuality and freedom, and not a moral or legal right to privacy. Personal information is characterized by Parent as factual (otherwise it would be covered by libel, slander or defamation), and these are facts that most persons choose not to reveal about themselves, such as facts about health, salary, weight, sexual orientation, etc. Personal information is documented, on Parent's view, only when it belongs to the public record, that is, in newspapers, court records, or other public documents. Thus, once information becomes part of a public record, there is no privacy invasion in future releases of the information, even years later or to a wide audience, nor does snooping or surveillance intrude on privacy if no undocumented information is gained. In cases where no new information is acquired, Parent views the intrusion as irrelevant to privacy, and better understood as an abridgment of anonymity, trespass, or harassment. Furthermore, what has been described above as the constitutional right to privacy, is viewed by Parent as better understood as an interest in liberty, not privacy. In sum, there is a loss of privacy on Parent's view, only when others acquire undocumented personal information about an individual. DeCew (1997) gives a detailed critique of Parent's position.

3.2 Privacy and Human Dignity

In an article written mainly as a defense of Warren and Brandeis' paper and as a response to William Prosser, Edward J. Bloustein (1964) argues that there is a common thread in the diverse legal cases protecting privacy. According to Bloustein, Warren and Brandeis failed to give a positive description of privacy, however they were correct that there was a single value connecting the privacy interests, a value they called "inviolate personality." On Bloustein's view it is possible to give a general theory of individual privacy that reconciles its divergent strands, and "inviolate personality" is the social value protected by privacy. It defines one's essence as a human being and it includes individual dignity and integrity, personal autonomy and independence. Respect for these values is what grounds and unifies the concept of privacy. Discussing each of Prosser's four types of privacy rights in turn, Bloustein defends

the view that each of these privacy rights is important because it protects against intrusions demeaning to personality and against affronts to human dignity. Using this analysis, Bloustein explicitly links the privacy rights in tort law described by Prosser with privacy protection under the Fourth Amendment. He urges that both leave an individual open to scrutiny in a way that leaves one's autonomy and sense of oneself as a person vulnerable, violating one's human dignity and moral personality. The common conceptual thread linking diverse privacy cases prohibiting dissemination of confidential information, eavesdropping, surveillance, and wiretapping, to name a few, is the value of protection against injury to individual freedom and human dignity. Invasion of privacy is best understood, in sum, as affront to human dignity. Although Bloustein admits the terms are somewhat vague, he defends this analysis as conceptually coherent and illuminating.

3.3 Privacy and Intimacy

A more common view has been to argue that privacy and intimacy are deeply related. On one account, privacy is valuable because intimacy would be impossible without it (Fried, 1970; Gerety 1977; Gerstein, 1978). Fried, for example, defines privacy narrowly as control over information about oneself. He extends this definition, however, arguing that privacy has intrinsic value, and is necessarily related to and fundamental for one's development as an individual with a moral and social personality able to form intimate relationships involving respect, love, friendship and trust. Privacy is valuable because it allows one control over information about oneself, which allows one to maintain varying degrees of intimacy. Indeed, love, friendship and trust are only possible if persons enjoy privacy and accord it to each other. Privacy is essential for such relationships on Fried's view, and this helps explain why a threat to privacy is a threat to our very integrity as persons. By characterizing privacy as a necessary context for love, friendship and trust, Fried is basing his account on a moral conception of persons and their personalities, on a Kantian notion of the person with basic rights and the need to define and pursue one's own values free from the impingement of others. Privacy allows one the freedom to define one's relations with others and to define oneself. In this way, privacy is also closely connected with respect and self respect.

Gerstein (1978) argues as well that privacy is necessary for intimacy, and intimacy in communication and interpersonal relationships is required for us to fully experience our lives. Intimacy without intrusion or observation is required for us to have experiences with spontaneity and without shame. Shoeman (1984) endorses these views and stresses that privacy provides a way to control intimate information about oneself and that has many other benefits, not only for relationships with others, but also for the development of one's personality and inner self. Julie Inness (1992) has identified intimacy as the defining feature of intrusions properly called privacy invasions. Inness argues that intimacy is based not on behavior, but on motivation. Inness believes that intimate information or activity is that which draws its meaning from love, liking, or care. It is privacy that protects one's ability to retain intimate information and activity so that one can fulfill one's needs of loving and caring.

3.4 Privacy and Social Relationships

A number of commentators defend views of privacy that link closely with accounts stressing privacy as

required for intimacy, emphasizing not just intimacy but also more generally the importance of developing diverse interpersonal relationships with others. Rachels (1975) acknowledges there is no single answer to the question why privacy is important to us, because it can be necessary to protect one's assets or interests, or to protect one from embarrassment, or to protect one against the deleterious consequences of information leaks, to name just a few. Nevertheless, he explicitly criticizes Thomson's reductionist view, and urges that privacy is a distinctive right. He basically defends the view that privacy is necessary to maintain a variety of social relationships, not just intimate ones. Privacy accords us the ability to control who knows what about us and who has access to us, and thereby allows us to vary our behavior with different people so that we may maintain and control our various social relationships, many of which will not be intimate. An intriguing part of Rachels' analysis of privacy is that it emphasizes ways in which privacy is not merely limited to control over information. Our ability to control both information and access to us allows us to control our relationships with others. Hence privacy is also connected to our behavior and activities.

3.5 Privacy and Restricted Access

Another group of theorists characterize privacy in terms of access. Some commentators describe privacy as exclusive access of a person to a realm of his or her own, and Sissela Bok (1982) argues that privacy protects us from unwanted access by others - either physical access or personal information or attention. Ruth Gavison (1980) defends this more expansive view of privacy in greater detail, arguing that interests in privacy are related to concerns over accessibility to others, that is, what others know about us, the extent to which they have physical access to us, and the extent to which we are the subject of the attention of others. Thus the concept of privacy is best understood as a concern for limited accessibility and one has perfect privacy when one is completely inaccessible to others. Privacy can be gained in three independent but interrelated ways: through secrecy, when no one has information about one, through anonymity, when no one pays attention to one, and through solitude, when no one has physical access to one. Gavison's view is that the concept of privacy is this complex of concepts all part of the notion of accessibility. Furthermore, the concept is also coherent because of the related functions privacy has, namely "the promotion of liberty, autonomy, selfhood, human relations, and furthering the existence of a free society" (Gavison 1980, 347).

Carefully reviewing these various views, Anita Allen (1988) also characterizes privacy as denoting a degree of inaccessibility of persons, their mental states, and information about them to the senses and surveillance of others. She views seclusion, solitude, secrecy, confidentiality, and anonymity as forms of privacy. She also urges that privacy is required by the liberal ideals of personhood, and the participation of citizens as equals. While her view appears to be similar to Gavison's, Allen suggests her restricted access view is broader than Gavison's. This is in part because Allen emphasizes that in public and private women experience privacy losses that are unique to their gender. Noting that privacy is neither a presumptive moral evil nor an unquestionable moral good, Allen nevertheless defends more extensive privacy protection for women in morality and the law. Using examples such as sexual harassment, victim anonymity in rape cases, and reproductive freedom, Allen emphasizes the moral significance of extending privacy protection for women. In some ways her account can be viewed as one reply to the

feminist critique of privacy, allowing that privacy can be a shield for abuse, but can also be so valuable for women that privacy protection should be enhanced, not diminished.

3.6 The Scope of Privacy

There is a further issue that has generated disagreement, even among those theorists who believe privacy is a coherent concept. The question is whether or not the constitutional right to privacy, and the constitutional privacy cases described involving personal decisions about lifestyle and family including birth control, interracial marriage, viewing pornography at home, abortion, and so on, delineate a genuine category of privacy issues, or merely raise questions about liberty of some sort. Parent (1983) explicitly excludes concerns about one's ability to make certain important personal decisions about one's family and lifestyle as genuine privacy issues, saying the constitutional right to privacy cases focus solely on liberty. Among the others who take this view are Henkin (1974), Thomson (1975), Gavison (1980), and Bork (1990). Allen (1988) defines privacy in terms of access and excludes from her definition protection of individual autonomous choice from governmental interference, which she terms a form of liberty. Yet she refers to this latter protection as "decisional privacy" and says determining its category is purely a definitional point and one of labels. Ultimately she believes interference with decisions involving procreation and sexuality raise the same moral concerns as other privacy intrusions, offending the values of personhood. The Supreme Court now claims (*Whalen v. Roe*, 429 U.S. 589, 1977) that there are two different dimensions to privacy: both control over information about oneself and control over one's ability to make certain important types of decisions.

Following this sort of reasoning, a number of theorists defend the view that privacy has broad scope, inclusive of the multiple types of privacy issues described by the Court, even though there is no simple definition of privacy. Most of these theorists explore the links between the types of privacy interests and the similarity of reasons for valuing each. Some stress that privacy is necessary for one to develop a concept of self as a purposeful, self determining agent. Privacy enables control over personal information as well as control over our bodies and personal choices for our concept of self (Kupfer, 1987). Some emphasize the importance of intimacy for all privacy issues, noting the need for privacy to protect intimate information about oneself, access to oneself, as well as intimate relationships and decisions about one's actions (Inness, 1992). Some focus on the importance of privacy norms that allow one to restrict others' access to them as well as privacy norms that enable and enhance personal expression and the development of relationships. Privacy provides protection against overreaching social control by others through their access to information or their control over decision making (Schoeman, 1992). Others suggest that privacy is best understood as a cluster concept covering interests in i) control over information about oneself, ii) control over access to oneself, both physical and mental, and iii) control over one's ability to make important decisions about family and lifestyle in order to be self expressive and to develop varied relationships (DeCew, 1997). These three interests are related because in each of the three contexts threats of information leaks, threats of control over our bodies, and threats to our power to make our own choices about our lifestyles and activities all make us vulnerable and fearful that we are being scrutinized, pressured or taken advantage of by others. Privacy has moral value because it shields us in all three contexts by providing certain freedom and independence - freedom from scrutiny,

prejudice, pressure to conform, exploitation, and the judgment of others.

3.7 Is Privacy Relative?

Schoeman (1984) points out that the question of whether or not privacy is culturally relative can be interpreted in two ways. One question is whether privacy is deemed valuable to all peoples or whether its value is relative to cultural differences. A second question is whether or not there are any aspects of life that are inherently private and not just conventionally so. Most writers have come to agree that while almost all cultures appear to value privacy, cultures differ in their ways of seeking and obtaining privacy, and probably do differ in the level they value privacy (Westin, 1967; Rachels, 1975). Allen (1988) is especially sensitive to the ways obligations from different cultures affect perceptions of privacy. There has been far less agreement on the second question. Some argue that matters relating to one's innermost self are inherently private, but characterizing this realm more succinctly and less vaguely has remained an elusive task. Thus it may well be that one of the difficulties in defining the realm of the private is that privacy is a notion that is strongly culturally relative, contingent on such factors as economics as well as technology available in a given cultural domain.

4. Privacy and Technology

The earliest arguments by Warren and Brandeis for explicit recognition of privacy protection in law were in large part motivated by expanding communication technology such as the development of widely distributed newspapers and multiply printed reproductions of photographs. Similarly Fourth Amendment protection against search and seizure was extended later in the twentieth century to cover telephone wiretaps and electronic surveillance. It is clear that many people still view privacy is a valuable interest and realize it is now threatened more than ever by technological advances. There are massive databases and Internet records of information about individual financial and credit history, medical records, purchases and telephone calls, for example, and most people do not know what information is stored about them or who has access to it. The ability for others to access and link the databases, with few controls on how they use, share, or exploit the information, makes individual control over information about oneself more difficult than ever before.

There are numerous other cases of the clash between privacy and technology. Consider the following new technologies. Caller ID, originally designed to protect people from unwanted calls from harassers, telemarketers, etc., involves privacy concerns for both the caller and the called. There is widespread mandatory and random drug testing of employees and others, although the Supreme Court has disallowed mandatory drug tests on pregnant women for use by police. Officials can now use heat sensors aimed through walls to detect such things as growing marijuana. Surveillance photos are commonly taken of those using Fast Lane, resulting in tickets mailed to speeding offenders, and similar photos are now taken at red lights in San Diego and elsewhere, leading to surprise tickets. Face scanning in Tampa, at casinos, and at large sporting events such as the Super Bowl, matches those photos with database records of felons, resulting in the capture of multiple offenders on the loose. Some rental car drivers are now

tracked by Global Positioning System (GPS) satellites, enabling car rental companies, not police, to levy stiff fines for speeding. Immigration officials in Australia are considering proposals to tag asylum seekers with electronic trackers before sending them into the community to await hearings. The media has recently uncovered an FBI Web surveillance system called Carnivore, that appears to sample the communications of as many Internet users as it chooses, not just suspects. Echelon, a covert global satellite network said to have the ability to intercept all phone, fax, and e-mail messages in the world, may have up to 20 international listening posts. Airline passengers will soon be able to go through customs with a two second biometric scan that confirms identity by mapping the iris of the eye, and U.S. airlines are considering using “smart cards” which will identify passengers by their fingerprints. There is a proliferation of biometric identification using faces, eyes, fingerprints, and other body parts for identifying specific individuals, and the technology for matching the information with other databases is advancing quickly. For many of these cases, it is possible to make a compelling argument for overriding the privacy intrusions. Drug and alcohol tests for airline pilots on the job seem completely justifiable in the name of public safety, for example. With the development of new and more sophisticated technology, however, recent work on privacy is examining the ways in which respect for privacy can be balanced with justifiable uses of new technology (Agre and Rotenberg, 1997; Brin, 1998; Etzioni, 2000). Moreover, in the wake of the terrorist attacks on September 11, 2001, it is likely that the literature on privacy will increasingly focus on how to balance privacy concerns with the need for public safety in an age of terrorism.

Legal Rights

Legal rights are, clearly, rights which exist under the rules of legal systems. They raise a number of different philosophical issues. (1) Whether legal rights are conceptually related to other types of rights, principally moral rights; (2) What the analysis of the concept of a legal right is; (3) What kinds of entities can be legal right-holders; (4) Whether there any kinds of rights which are exclusive to, or at least have much greater importance in, legal systems, as opposed to morality; (5) What rights legal systems ought to create or recognise. Issue (5) is primarily one of moral and political philosophy, and is not different in general principle from the issue of what duties, permissions, powers, etc, legal systems ought to create or recognise. It will not, therefore, be addressed here.

A preliminary point should be mentioned. Do all legal systems have a concept of rights? Their use is pervasive in modern legal systems. We talk of legislatures having the legal right to pass laws, of judges to decide cases, of private individuals to make wills and contracts; as well as of constitutions providing legal rights to the citizens against fellow citizens and against the state itself. Yet it has been suggested that even some sophisticated earlier systems, such as Roman law, had no terminology which clearly separated rights from duties (see *Maine* (1861), 269-70). The question is primarily one for legal historians and will not be pursued here, but it may be remarked that it may still be legitimate when describing those systems to talk of rights in the modern sense, since Roman law, for example, clearly achieved many of the same results as contemporary systems. Presumably, it did so by deploying some of the more basic concepts into which rights can, arguably, be analysed.

---

1. Are Legal Rights Conceptually Related to Other Types of Rights?

The position of many important writers on legal rights is difficult to ascertain on this point, because it is not one they addressed directly. Hohfeld (1919), for example, confined his discussion entirely to legal rights and never mentioned moral ones. Hart did write about moral rights (1955, 1979) as well legal ones (1973, 1994), but not in a way that allows for much direct comparison. Bentham (1970 [1782]) wrote extensively about the analysis of legal rights, but, notoriously, thought that the idea of natural moral rights was conceptual nonsense.

Mill (1969 [1861]), whilst endorsing Bentham's overall Utilitarian position, did not share his scepticism about moral rights, and seems to have thought that moral and and legal rights were, analytically, closely connected - "When we call anything a person's right, we mean that he has a valid claim on society to protect him in the possession of it, either by the force of law, or by that of education and opinion." Those things which ought to be so protected were, in his view, those which concerned the fundamentals of human well-being, and were therefore a sub-set of those things which a person ought to have on grounds of utility.

Whilst not necessarily sharing Mill's view about all rights being related to fundamentals of well-being, many contemporary writers (e.g., Raz (1984a, 1984b), Wellman (1985, 1995)) agree that the core concept of a right is something common to law and morality, though some have argued that jurisprudential writers, particularly Hohfeld, provide a better and clearer starting-point for general analysis than previous writers in moral philosophy. The view that the core concept is common to both would appear to be consistent with maintaining that, nevertheless, in terms of justification in practical reasoning, legal rights should be based on moral ones.

2. The Conceptual Analysis of Legal Rights

Not all philosophers have agreed that rights can be fully analysed. White (1984), for example, argued that the task is impossible because the concept of a right is as basic as any of the others, such as duty, liberty, power, etc (or any set of them) into which it is usually analysed. He agrees, however, that rights can in part be explained by reference to such concepts. White's approach, based largely on close linguistic analysis, has remained something of a minority one.

The remaining approaches can be categorised in different ways, but a main division is between those who think that rights are singled out by their great weight as practical reasons, and those who think that rights are not special in this regard, but instead are to be analysed into duties, permissions, powers, etc, or some combination of these, perhaps with the addition of other conditions.

Dworkin (1973, 1975, 1981, 1986) has been the principal proponent of the first view. According to him rights enjoy a categorial priority in weight over any other consideration which is not itself right-based. Clearly, it is true of many legal systems that constitutional rights, or some of them, should outweigh any other consideration which is not itself derived from a constitutional right. But that seems to be primarily because of the constitutional status of the right. Both in law and in morality many rights are of a rather

trivial nature. In morality such rights can, arguably, sometimes be justifiably outweighed even by considerations of personal convenience (cf. Raz (1978)). Similarly in law it seems that many *prima facie* rights can be defeated by what the court regards as considerations of the general interest. Dworkin's (1977) response to the latter type of criticism has been to argue that, on closer inspection, the consideration opposing the right can be seen as itself an instantiation of another general right. But this depends on the contentious claim that the only considerations that courts can justifiably rely upon are pre-existing rights. The objection has also been raised that, as a general theory of the nature of rights, it risks being self-defeating, since any consideration whatsoever can then be argued to be right-based, which leaves rights with no special role in practical reasoning.

Most writers have, instead, favoured the view that rights are to be analysed into other, more basic, notions, principally those of duty, permission and power, with perhaps the addition of other criteria. This means that not all rights will be of great importance. Their importance will vary with the strength of the grounds for the duty, permission or power. Before looking more closely at these accounts, another point should be mentioned. Theorists are divided between those who think that rights are, as it were, the 'reflex' of the duty, permission or power, and those who think that the right has a priority over them. The question is whether the duty, etc, grounds the right, or the right the duty. Most older writers (e.g., Bentham, Austin, Hohfeld, Kelsen) appear to have adhered to the first view, whilst more recent writers (e.g., MacCormick, Raz, Wellman) take the second. The second view has the implication that the force of a right is not necessarily exhausted by any existing set of duties etc, that follow from it, but may be a ground for creating new duties as circumstances change. This latter view seems to accord better at least with the way that constitutional legal rights work.

Amongst those who think that rights can be analysed, at least in part, into duties, permissions and powers, there is a further main division. Some think that the essence of a right is to have choice or control over the corresponding duty etc. Others think that the main thing is that one's interests are protected by the duty etc. Hart and Wellman are amongst the proponents of the first view, Bentham, Austin, MacCormick and Raz are amongst those maintaining some version of the second.

An outline of Hart's (1973) theory may be given as an illustration of the first view. According to Hart, someone (call him '*X*') may be a legal right-holder primarily in one of two ways. First of all, *X* may have a bilateral permission to perform some action, i.e., *X* is permitted both to *A* and to not-*A* (together with there being some prohibitions on others interfering). Secondly, someone else may have a duty (e.g., to pay *X* £10) over which *X* has control, primarily by waiving or enforcing it. Since *X* has a choice in each case that explains why he is referred to as being a right-holder. One difficulty about this kind of theory is to explain our apparent reference to rights when there is no choice, eg when one is not only entitled to vote in elections, but also obliged by law to do so.

Two different versions of the interest theory can be seen, corresponding to the question about the priority of rights mentioned above.

According to older versions, such as those of Bentham and Austin, *X* is a right-holder because he is the beneficiary, or intended beneficiary, of another's duty, or perhaps of the absence of a duty on him which

the law might otherwise have imposed. For example, if *X* has a right to be paid £10 by *Y*, then this is explained by saying that *Y* has a duty, the performance of which (handing over the £10) is intended to benefit X. One problem about this theory is to explain why the criminal law, although it may in part exist to protect moral rights, is not generally regarded as directly conferring legal rights on individual citizens, despite the fact that they are intended beneficiaries of the corresponding duties. (There may, of course, in many systems be parallel civil law rights, but that is a contingent matter. See more on this point below.)

A more modern version of this theory was proposed by MacCormick (1977), who argued that a right-holder was the intended beneficiary of a specific share of benefit, rather than just being a generalised beneficiary of the rules. However, even with this amendment, it remains difficult to explain third party rights under contracts. Suppose *X* and *Y* enter into a contract which imposes duties on each of them with the intention that performance of these will benefit *Z*. According to the theory, *Z* must (conceptually) be a legal right-holder. But it is in fact an entirely contingent matter as to whether *Z* is or not. Some legal systems recognise *Z* as having rights in such a situation and others do not. In Britain, for example, Scots Law recognised such rights under certain conditions, but English Law did not until the English position was recently changed by statute.

More recent versions, such as those of Raz (1984a, 1984b), take a different tack altogether. According to them, to say that *X* is a right-holder is to say that his interests, or an aspect of them, are sufficient reason for imposing duties on others either not to interfere with *X* in the performance of some action, or to secure him in something. This, *inter alia*, gets round the third-party rights' problem, because the explanation is simply that it is all a question of whether the system recognises the interests of *Z* as part of the reason for *X* and Y's duties, or whether it is only the interests of *X* and *Y*. Raz (1997) has emphasised that this does mean that only the right-holder's interests are relevant to the question of whether something should be recognised as a right. Considerations of the general or common interest may be relevant too.

A number of subsidiary questions can be raised.

Firstly, should rights be analysed solely in terms of duties on others (together with some other condition), or do we need to bring in also other concepts, such as permission, power and immunity? Hohfeld thought that, strictly speaking, something was a legal right only if it corresponded to a duty on another, but he argued that legal usage was often confusing because the reference was really to one of the other concepts. Thus, in his view, the law sometimes also said that *X* had a right if (1) he had a permission to *A*, (2) he had a legal power to *A*, (3) *Y* had no legal power to affect him.

Waldron (1981) and Raz (1984a, 1984b) have been exponents of the view that rights should be seen as giving rise only to duties. Hart (1973), following Bentham, had argued that a liberty-right should be seen as a bilateral permission to A together with duties on others not to interfere with *X*'s A-ing. Waldron and Raz argue that it is an important feature of rights that they entitle the right-holder to do not only that which is right, but also (within bounds) that which is wrong. This they regard as best explained by seeing rights as imposing only duties of non-interference on others, not as granting the right-holder a permission. An alternative view (Campbell 1997) is to see some rights as indeed granting permissions,

but to point out that in granting a legal permission the law is not saying that there may not be reasons against performing the action, only that (within the bounds of the permission) the law will act as if there were not.

Powers raise a different issue. Many writers (e.g., Hohfeld, Hart (1973)) have considered them as being a type of right. By a legal power we mean the ability to bring about changes in legal rules or their application (plus some further conditions). Usually, of course, the lawmaker in granting a power also grants a right to exercise it, but occasionally this is not so, for example where the exercising of the right would itself be a crime or a civil wrong. In English Law, for example, until the position was recently changed by statute, a thief had, in certain special circumstances, the legal power to pass good title in the goods he had stolen to a third party, even though by doing so he committed a civil, and possibly also a criminal, wrong. This seems to indicate that powers should not be thought of as being rights themselves.

Powers also illustrate a general problem about the analysis of legal rights, and arguably of rights in general. Namely that of whether an element should be seen as part of the very essence of the concept of a right, or whether it is merely an element in that which is (contingently) its content, i.e., that which there is a right to do or have.

Relatedly, of the four fundamental types of rights which Hohfeld claimed to identify, immunities raise problems, though somewhat different ones. An immunity arises when *Y* has no power to change X's legal position. But is an immunity itself a right or is it simply a means of protecting a right, i.e., by making it immune from removal or alteration? As with powers, views have differed about this.

3. What Kinds of Entities Can be Legal Right-holders?

There has been much dispute amongst philosophers as what to kinds of entities can be right-holders. Corresponding pretty much to the general dispute about the very nature of rights, some have argued that any entity which would benefit from the performance by others of legal duties can be a right-holder; others that it has to be an entity which has interests; others that it has to be a entity capable of exercising some kind of control over the relevant legal machinery. And there are variants of all these positions.

There has to be a sense in which legal systems can confer rights on such entities as they please. This is because it has long been recognised that legal systems can regard as legal persons such entities as they please. In England, for example, 'the Crown' has, for centuries, been regarded as a legal entity, although what this means in terms of office-holders, far less the actual human beings who occupied those offices, has changed greatly over that time. Likewise, all modern societies recognise the legal existence as persons of companies or corporations and frequently of such entities as trade unions, government departments, universities, certain types of partnerships and clubs, etc.

One of the most contentious areas in recent years has been whether young children, the severely mentally

ill, non-human animals, areas of endangered countryside, etc, can properly be regarded as being legal right-holders. Clearly anyone who has *locus standi* before a court must be a holder of some rights within the system. But it does not seem to follow automatically that an entity which does not, or which is physically or mentally incapable of bringing a legal action, is not thereby a right-holder. For it may be the intention of the system that the interests of that entity should be represented by another person. Given then, that all these entities may be protected by law, and that someone can bring some kind of legal action to ensure that those duties are enforced, when would we say that the entity itself is a right-holder and when not?

The answer will often turn upon whether one embraces an interest- or a choice-theory of rights. MacCormick (1976), for example, argued that any theory of rights which could not accommodate childrens' rights must be deficient, and this was a reason, in his view, for adopting an interest theory. Wellman (1995), on the other hand, claims that to assert that very young children or the severely mentally ill can have legal rights is to distort the concept of a right, since they lack the relevant control of the legal machinery. Instead, he argues, the relevant rights should be seen as belonging only to those who can bring the relevant actions on their behalf. For example, in his view a very young child would not have a right not to be negligently injured by the conduct of another. Rather, it would be the case that the child's parent had a right that their child not be negligently injured. One difficulty about this position appears to be that it does not easily square with the relevent remedial rights (e.g., to damages) that the law would recognise. In this example the law would clearly compensate the child's loss in being injured, not the parent's loss in their child being injured (though the latter might be a separate ground of action in some systems).

4. Exclusivity of Rights

The issue here is: whether there are any fundamental aspects of rights which are exclusive to, or at least more important in, legal systems, as opposed to morality.

Five particular sub-issues may be raised here.

4.1 Primary and Remedial Rights

Remedial rights are those which arise because of a breach of a primary one. Clearly they arise also outside the law, for example by the duty to apologise or make amends even if there is no legal obligation to do so. But legal remedial duties are generally more precise, and, just by the nature of law, institutionalised.

It is one of the main functions of legal systems to provide remedies for breach (or sometimes anticipated breach) of the primary rights which they confer. So if someone is injured by the negligence of another there will usually arise a remedial right to damages. If he is killed there may arise in members of his family an independent right to compensation, and so on. Other types of remedial right can include those

for court orders requiring the party at fault to execute, or refrain from, some particular course of action, very often that which they had a duty to do, or to refrain from, under the primary right. Such rights are often very complex in the detail. For example the measure of damages may be different if the wrongful act is a tort/delict, as opposed to a breach of contract. Likewise, in many systems, some remedies must be granted as a matter of right whilst others are at the discretion of the court. By way of illustration of the remedies in the two British legal systems, reference may be made to Lawson (1980) and Walker (1974).

Usually remedial rights will themselves have further remedial rights attached, for example, to have the court impose a more coercive order, perhaps with the threat of a criminal or quasi-criminal sanction, or to have a person's assets frozen or confiscated, in the event, for example, that someone has failed to pay damages previously awarded by the court. The details of these further remedial rights vary from system to system.

A related, more controversial, point is as to whether criminal, as opposed to civil, law confers any legal rights on the citizens protected by it. The orthodox view is that it does not, although there may well be a parallel civil right. Take the case of someone who is wrongfully assaulted. In most legal systems this will be both a crime and a tort/delict. The civil law clearly gives a remedial right, eg. to sue for damages. But since, in most jurisdictions, it is mainly (and sometimes exclusively) the state which decides whether to prosecute for the criminal aspect, the more usual view is that the citizen has no legal right corresponding to the criminal aspect.

The issue is often complicated, legally, by the absence of clear indication from the legislature as whether it intended, by a particular statute, to create only a crime or also to confer civil law rights on citizens. A further complication can be that criminal courts sometimes exercise a quasi-civil function (e.g., to make a restoration or compensation order after a conviction for theft), and *vice versa* (e.g., the power of a civil court to award punitive or exemplary damages).

This issue is different from that of whether criminal law can act to recognise and protect moral rights. It seems possible to suggest that it can, since moral rights can be protected not only by legal rights, but also by legal duties on others (without corresponding legal rights). For example, a legal system could create a criminal offence of harrassment in order to protect a moral right to privacy, without thereby necessarily recognising a legal right to privacy, i.e., something which would act as a positive reason in favour of privacy in interpreting unclear rules, or in developing the law.

4.2 Conditional Rights

In the case of many legal rights a condition has to be satisfied for their possession or exercise. This, in itself, does not make legal rights different from many moral ones. Just as one has a legal right to damages for assault only if one has been assaulted, one has a moral one to an apology for being insulted only if one has been insulted. But legal rights can give rise to more complicated situations, which rarely arise in morality.

In the above examples we can say that the right-token, as opposed to the right-type, comes into existence only when the condition for its instantiation is triggered. But legal systems sometimes say that that the right-token exists before one of the conditions for the exercise of the right exists. Essentially, it is the difference between saying "if *p*, *X* has a right to *A*" and "*X* has a right, if *p*, to *A*." In the latter case the implication is that the right-token exists now, not just that it will exist. Why should we say this? One proposed answer is that legal systems, unlike morality, have devised sets of rules for transmission of rights even before the triggering condition for the exercise of the right has arrived.

Suppose, for example, that *X*, under his will, left a sum of money to *Y*, on condition that *Y* had attained the age of 21. It may be that the correct way of understanding the provision, under the rules of the legal system, is that only if *Y* had attained 21 when *X* died does he have a right to the money. But it may be that the correct way of understanding it as saying that *Y*, even if he has not attained 21 when *X* dies, acquires a right to the money, but it is to be paid only when he is 21. One practical difference is that in the latter case the right can pass to Y's successor in title if *Y*, having survived *X*, nevertheless dies before he is 21. In the latter case, lawyers describe the right as 'vested.' There can be many complex legal rules relating to this type of situation, and they vary greatly from jurisdiction to jurisdiction. Reference should be made to textbooks, primarily on testamentary succession, in the jurisdiction.

4.3 Property Rights

A further particular kind of legal rights, or group of rights, which has received an increasing amount of attention from theorists is that of property rights. Discussion of this belongs more properly to that of property itself -- see the entry on property. Only some very brief points will be made here.

The first is as to whether property rights, and hence the concept of property, are essentially legal in their nature, or whether they are more general social phenomena which are simply recognised and protected by law in all modern societies. According to Bentham (1843) " … there is no natural property … property is entirely the creature of the law." Bentham's argument is essentially that what we mean by property is security of expectation in being able to keep, sell, use, etc, objects, and only the law can guarantee such security.

On the other hand, it is certainly possible to talk coherently about property in a way that does not necessarily correspond to the legal position. A parent may for example say to a young child that a certain toy is theirs, though in law it is the parent's. Likewise it may be plausible to claim that concepts of ownership and possession, though they may be less securely protected, can exist in societies which do not have anything that we normally recognise as a fully-fledged legal system. Some people will perhaps regard these kind of examples as indications that the concept of property is not essentially legal, whilst others may incline to the view that these are simply metaphorical extensions of a concept which is legal *au fond*.

Secondly, it should be noted that, in law, property rights can be of many different types. Although ownership is obviously one of the most important, another major class is that of possession, whether

temporary or relatively permanent. For example, the right to use a car which one has hired for a week or to live in a certain house for the rest of one's life. Yet other types, falling short of either ownership or possession, could be, for example, to walk across the local farmer's field or have one's next-door neighbour maintain his side of the joint garden wall.

The details of property rights vary from jurisdiction to jurisdiction perhaps more than those of almost any other types of right. Further, many jurisdictions have different rules relating to property rights in land (and its fixtures) as opposed to all other types of entity. For these details reference should be made to specialist books in the jursdiction.

Even when considering just ownership, there is debate amongst theorists as to how this should be analysed. Some see it as essentially a cluster of other property rights of particular content, such as those to possession, income, etc, whilst others see it as being basically a structural relation between rights, content being comparatively irrelevant. For example as being the person to whom possession or use, even though those may presently belong to others, would ultimately return if a certain series of contingent events were to occur.

For further discussion of property in a philosophical context see Honore (1960, 1961), Becker (1977), Waldron (1988), Munzer (1990), Campbell (1992), Harris (1996), Penner (1997). (Some of these are concerned more with the moral justification of ownership.)

4.4 Subjective Rights

The above account of rights has been written largely from the point of view of Anglo-American law and philosophy. It should, however, be mentioned that there is one aspect of legal rights which is to be found amongst the European Continental writers, but of which there is no trace in the Anglo-American tradition. That is the description of rights as being 'subjective' (*droits subjectifs*; *subjektives Rechten*).

In French and in German the same word (*droit*, *Recht*) serves as the noun which refers both to rules of law and the rights which are created by them, and therefore disambiguation is required.

In French law the distinction is drawn by distinguishing between *le Droit objectif* (the noun spelt with a capital according to some, but not all, writers) and *les droits subjectifs*. (For general discussion see, for example, Cornu 1996). However, French law seems at the same time to confine the term '*droits subjectifs*' to a sub-class of legal rights, namely rights which are primarily those of private citizens, eg to make a will or contract. The term appears not to extend to such rights as those of a government agency owning property or a government minister making a legal order under delegated powers.

German law seems to draw a basically similar distinction between '*das Recht*' and '*subjectives Rechten*' (see, for example, Dietel 1983).

4.5 Means of Conferring Legal Rights

Many of the issues relating to this are not confined to rights, but are shared with duties and powers, so only a brief outline will be given.

In most modern legal systems certain fundamental rights are conferred by the constitution. This usually gives them a certain degree of priority over competing legal considerations, but this can vary from system to system. Sometimes constitutional rights will have an absolute priority over any other consideration not itself based on a constitutional right. Sometimes they will merely favour one legal outcome rather than another, without dictating it.

Constitutions will vary, too, as to whether certain rights are ‘entrenched’ or not. Entrenchment can be absolute, in which case the rights cannot be removed or altered by any constitutional means (as is the case with some of the ‘basic rights’ in the German Constitution), or it can be relative, requiring only a more onerous procedure than that for normal legislation (as with the Constitution of the USA.).

Constitutions will also vary on the extent to which human rights recognised under international law or treaty are recognised in national law. For example, in some countries in Europe, the European Convention on Human Rights, and decisions of the European Court of Human Rights thereon, are incorporated into national law and override any national law inconsistent with them. In others, such as the United Kingdom, the courts have, so far as possible, to interpret legislation to be consistent with the Convention, but have no power to strike it down if they find it to be clearly inconsistent.

Other rights can be conferred by normal legislation or by common law (ie. the tradition of judge-made law). One interesting point is that, arguably, many legal rights are conferred by no positive law, but arise simply from the absence of any law to the contrary. That is, it is probably a practical necessity that every legal system has an unwritten ‘closure rule’ to the effect that whatever is not prohibited is permitted. If some types of rights are essentially permissions, then many such rights arise in this way. In most legal systems my right to cross the street, for example, is of this nature. Probably no positive law will say that I can do so, and possibly no more general enacted right will imply it.

Philosophy and Christian Theology

Many of the doctrines and concepts central to Christianity have important philosophical implications or presuppositions. In this article we will take a closer look at some of the central doctrines and concepts, and their philosophical relevance.

Of course, many philosophically laden doctrines and concepts are relevant to Christianity, and we cannot discuss them all here. Rather, our focus will be on those concepts and doctrines that are distinctively Christian, and which have been the focus of a good deal of recent discussion in the philosophical literature. Thus, although theism is a central Christian concept, it is not *distinctively* Christian and so will not be covered here. Further, although views about the Eucharist, a central Christian concept, have held a significant place in the philosophical dialogue in former times, it will not be discussed here since it has not been a significant focus of recent discussions. As a result, we will concentrate on three distinctive and central Christian concepts which have received significant attention in the recent literature: the doctrines of the Trinity and the Incarnation, and views on the nature of atonement.

1. Philosophy and Christian Theology

Before we begin, it is worthwhile to consider in brief the general relationship between philosophy and Christian religious dogma. In the history of Christian theology, philosophy has sometimes been seen as a natural complement to theological reflection, while at other times the advocates for the two disciplines have regarded each other as mortal enemies. Some early Christian thinkers such as Tertullian were of the view that any intrusion of secular philosophical reason into theological reflection was out of order. Thus, even if certain theological claims seemed to fly in the face of the standards of reasoning defended by philosophers, the religious believer should not flinch. Other early Christian thinkers, such as St.

Augustine of Hippo, argued that philosophical reflection complemented theology, but only when these philosophical reflections were firmly grounded in a prior intellectual commitment to the underlying truth of the Christian faith. Thus, the legitimacy of philosophy was derived from the legitimacy of the underlying faith commitments.

Into the High Middle Ages, Augustine's views were widely defended. It was during this time however that St. Thomas Aquinas described another model for the relationship between philosophy and theology. According to the Thomistic model, philosophy and theology are distinct enterprises. The primary difference between the two is their intellectual starting points. Philosophy takes as its data the deliverances of our natural mental faculties: what we see, hear, taste, touch, and smell. These data can be accepted on the basis of the reliability of our natural faculties with respect to the natural world. Theology, on the other hand takes as its starting point the divine revelations contained in the Bible. These data can be accepted on the basis of divine authority, in a way analogous to the way in which we accept, for example, the claims made by a physics professor about the basic facts of physics.

On this way of seeing the two disciplines, if at least one of the premises of an argument is derived from revelation, the argument falls in the domain of theology; otherwise it falls into philosophy's domain. Since this way of thinking about philosophy and theology sharply demarcates the disciplines, it is possible in principle that the conclusions reached by one might be contradicted by the other. According to advocates of this model, however, any such conflict must be merely apparent. Since God both created the world which is accessible to philosophy and revealed the texts accessible to theologians, the claims yielded by one cannot conflict with the claims yielded by another unless the philosopher or theologian has made some prior error.

Since the deliverances of the two disciplines must then coincide, philosophy can be put to the service of theology (and perhaps vice-versa). How might philosophy play this complementary role? First, philosophical reasoning might persuade some who do not accept the authority of purported divine revelation of the claims contained in religious texts. Thus, an atheist who is unwilling to accept the authority of religious texts might come to believe that God exists on the basis of purely philosophical arguments. Second, distinctively philosophical techniques might be brought to bear in helping the theologian clear up imprecise or ambiguous theological claims. Thus, theology might provide us with information sufficient to conclude that Jesus Christ was a single person with two natures, one human and one divine, but leave us in the dark about exactly how this relationship between divine and human natures is to be understood. The philosopher can provide some assistance here, since, among other things, he or she can help the theologian discern which models are, for example, logically inconsistent and thus not even candidates for understanding the relationship of divine and human natures in Christ.

For most of the twentieth century, the vast majority of English language philosophy went on without much interaction with theology at all. While there are a number of complex reasons for this divorce, three are especially important. The first is that atheism was the predominant opinion among English language philosophers throughout much of that century.

A second, quite related reason is that, philosophers in the twentieth century regarded theological language as either meaningless, or, at best, subject to scrutiny only insofar as that language had a bearing on religious practice. The former belief (i.e., that theological language was meaningless) was inspired by a tenet of logical positivism, according to which any statement that lacks empirical content is meaningless. Since much theological language, for example, language describing the doctrine of the Trinity, lacks empirical content, such language must be meaningless. The latter belief, inspired by Wittgenstein, holds that language itself only has meaning in specific practical contexts, and thus that religious language was not aiming to express truths about the world which could be subjected to objective philosophical scrutiny.

The third reason is that a great deal of academic theology moved away from defending the claims of orthodox Christian theism in traditional ways, often seeking devices for re-interpreting these claims in ways congenial to contemporary modes of thought which often ran contrary to the methods employed in analytic philosophy.

In the last twenty years, however, philosophers have returned to many of the traditional claims of orthodox Christianity and have begun to apply the tools of contemporary philosophy in ways that are somewhat more eclectic than those described in the Augustinian or Thomistic models described above. In keeping with the recent academic trend, contemporary philosophers of religion have been unwilling to maintain hard and fast distinctions between the two disciplines. As a result, it is often difficult in reading recent work to distinguish what the philosophers are doing from what the theologians of past centuries regarded as strictly within the theological domain. However, like theologians of the medieval period, much recent work in philosophy of religion seems to fall into one of two categories. The first category includes attempts to demonstrate the truth of religious claims by appeal to evidence available apart from purported divine revelations. The second category includes attempts to demonstrate the consistency and plausibility of theological claims using philosophical techniques. In what follows, we will be considering work that falls into this second category.

2. Trinity

From the beginning, Christians have affirmed the claim that there is one God and that three persons are God: God the Father, God the Son, and God the Holy Spirit. In AD 675, the Council of Toledo framed this pair of claims as follows:

> Although we profess three persons we do not profess three substances but *one substance* and three persons … If we are asked about the individual Person, we must answer that he is God. Therefore, we may say God the Father, God the Son, and God the Holy Spirit; but they are not three Gods, he is one God … Each single Person is wholly God in himself and … all three persons together are one God.

Such formulations set forth the Christian doctrine of the Trinity. Cornelius Plantinga, Jr., reflecting on the Council of Toledo's profession, remarks that it “possesses great puzzling power” (Plantinga 1989, 22). No doubt this is an understatement. The Christian doctrine is puzzling, and this has led some of Christianity's

critics to advance the claim that it is, in fact, incoherent.

Perhaps the initial puzzling power of the doctrine of the Trinity is not immediately obvious. After all, someone might think that one thing, Fred, can be “many things” all at the same time, for example, a butcher, a baker, and a candlestick maker. So why can't God be Father, Son, and Holy Spirit all at the same time? Likewise, multiple distinct things can all be “one thing” at the same time. Thus, each member of the Baltimore Orioles baseball team can be Orioles taken individually, as well as “the Orioles” taken collectively. One might then think that defenders of the Trinity might be able to construct models out of such examples that would preserve the logical coherence of the doctrine. But things will not be quite that easy. To see why, we can take a brief detour and then come back to the two examples above.

Traditional Christian theologians have held that however the doctrine of the Trinity is understood, there are two extreme positions that are to be ruled out. These positions are *modalism* and *tritheism*. According to modalism, God is one single entity, object, or substance, and each person of the Trinty is simply a mode or a “way in which the one divine substance manifests itself.” This view has been rejected because it seems to sacrifice the distinctness of the divine persons in order to maintain the notion of divine unity. According to tritheism, on the other hand, the divine persons are each distinct individual persons which are so closely related that they together count as a single thing in some fashion. Nonetheless, despite this oneness, the three persons are still three gods. This view has been rejected for the opposite reason, namely, it preserves the distinctness of persons without maintaining any robust sense of the “oneness” of God.

One can now see why the “butcher, baker, candlestick maker” and the “Orioles” examples will not help us in providing a model for the Trinity. The first, like modalism, leans too heavily towards oneness at the expense of the distinctness of the three persons. It holds, that is, that there is really only one Fred, but that Fred can manifest himself in different ways by carrying out three different tasks. The second, like tritheism, leans too far in the opposite direction. On this example, the individual Orioles only form the “single team” because of certain agreements they have made to act cooperatively on the baseball team. There is no genuine, organic unity here.

Nonetheless, most models of the Trinity that have been proposed and defended have leaned in modalist or tritheistic directions. In order to help sort out which models can be regarded as plausible, one needs first to get clear about just what the Christian means to affirm in confessing the existence of three persons and one God. What is “a person” according to the doctrine, and what is “a God”? One can easily see some initial difficulties in even these questions. Even if we can come up with a single coherent description of God, we are still left with the ambiguous notion of person. Sometimes we use the word “person” in a metaphysical sense, to refer to an individual, rational substance. Other times we use it in a psychological sense to refer to a “center of consciousness or rational awareness.” In other cases we might have in mind a functional notion of person, according to which a person is whatever sort of thing is capable entering into certain sorts of relationships, such as love, friendship, and so forth. Or we might use “person” in a moral or forensic sense, according to which a person is a subject or moral accountability, praise, or blame. And there are others.

Since Christians claim that the doctrine of Trinity is discovered through divine revelation, perhaps the relevant conception of person should be drawn from revealed texts. Unfortunately, the Bible itself does not seem to narrow down the alternatives to a single candidate. As a result, there is a good deal of remaining latitude in constructing a model for the Trinity.

Recent defenses of orthodox conceptions of the Trinity understand the notion in a way that highlights the centrality of persons as distinct centers of rational, conscious, and morally significant volitional activity. Most have concluded that this conception of personhood is incompatible with regarding the three divine persons as somehow mere aspects or modes of presentation of an underlying singular entity. As a result, these recent defenses have leaned in the direction of regarding the divine persons as distinct entities whose unity arises in virtue of certain necessary relations that exist among them. In this way, these models lean more in the tritheistic direction. Still, the necessary relations that these models attribute to the divine persons unify them in special and unique ways.

Richard Swinburne, for example, defends a view according to which each of the three divine persons has all of the essential characteristics of divinity: omniscience, omnipotence, omnipresence, moral perfection, and so forth (Swinburne 1994, ch. 8). He further claims that the persons have necessarily harmonious wills, so that their volitions never come into conflict, and that there is a perfectly loving relation that also necessarily obtains among them. Further, this view is compatible with traditional claims of dependence relations among members of the Trinity. Traditional formulations of the doctrine hold that the Father *generates* the Son and that Father and Son jointly give rise to (or *spirate*, literally “breathe forth”) the Holy Spirit. Such relations are possible as long as one causes the other in such a way that the causing relation has always obtained, and it is impossible for the relation not to obtain.

On this sort of view, there is one God because the community of divine persons is so closely inter-connected that, though they are three distinct persons, they nonetheless count as a single entity in another respect. For if we were to consider a set of three human persons, for example, who exhibited these characteristics of necessary unity, volitional harmony, and love, it is hard to regard them as distinct in the way we do ordinary persons. And that is, of course, just what the doctrine aims to put forth.

Perhaps this view seems to lean too strongly in the tritheistic direction. How could the social Trinitarian respond to this worry? One way would be to focus attention on exactly what is required in order for many “things” to jointly constitute another single “thing.” My (one) body is composed of (many) atoms. My (one) car is composed of (many) parts. In order to assess whether or not social Trinitarianism is viciously tritheistic, one needs to ask what principles govern the relationship between parts and wholes generally. We know many atoms can make a single body and many ingredients can make a single cake. Can many persons constitute a single divine entity? One thing is sure: the answer is not an obvious “no.” And this, perhaps, leaves the door open for the social Trinitarian to make the case that divine unity is not lost on his view after all. Saving such unity, however, will require more metaphysical work.

3. Incarnation

The doctrine of the Incarnation concerns Jesus Christ, the second person of the Trinty. Specifically, the doctrine holds that, at a time roughly two thousand years in the past, the divine person took on himself a second, fully human nature. As a result, he was a single person in full possession of two distinct natures, one human and one divine. The Council of Chalcedon in 451 put forth the canonical statement of the doctrine as follows:

> We confess one and the same our Lord Jesus Christ … the same perfect in Godhead, the same in perfect manhood, truly God and truly man … acknowledged in two natures without confusion, without change, without division, without separation–the difference of natures being by no means taken away because of the union, but rather the distinctive character of each nature being preserved, and combining into one person and hypostasis—not divided or separated into two persons, but one and the same Son and only begotten God, Word, Lord Jesus Christ.

Critics have held this doctrine to be “impossible, self-contradictory, incoherent, absurd, and unintelligible.” The central difficulty for the doctrine is that it seems to attribute to one person characteristics that are not logically compatible. For example, it seems on the one hand that human beings are necessarily created, finite, not-omnipresent, not-omniscient, not-omnipotent, and so forth. On the other hand, divine beings are essentially the opposite of all those things. Thus, one person could bear both natures, human and divine, only if such a person could be both finite and not-finite, created and uncreated, and so forth. And this is surely impossible.

Two main strategies have been pursued in an attempt to resolve this apparent paradox. The first is the *kenotic* strategy. The kenotic view (from the Greek *kenosis* meaning ’to empty’) finds its motivation in a New Testament passage which claims that Jesus “who, though he was in the form of God, did not count equality with God a thing to be grasped, but emptied himself, taking the form of a servant, being born in the likeness of men. And being found in human form he humbled himself and became obedient unto death…” (Phillipians 2:6-8). According to this view, in becoming incarnate, God the Son voluntarily and temporarily laid aside some of his divine attributes in order to take on a human nature and thus his earthly mission.

The main difficulty with this basic version of the kenotic view is that it entails that a thing can lay aside properties essential for it's being a member of a certain kind and still remain a member of that kind. In other words, it allows that God the Son could (temporarily) be non-omnipotent, non-omniscient, and so forth, and still be God. But if those attributes are *essential* to divinity, that is, essential for something's being counted as God, then this solution is simply mistaken. Some have offered more refined versions of the kenotic theory, arguing that the basic view mischaracterizes the divine attributes. Rather, God's properties should be characterized as: omniscient-unless-incarnate, omnipotent-unless-incarnate, and so forth. Thus, when the powers of omnipotence are laid aside at the incarnation, Jesus can be fully human while retaining *these* divine attributes without contradiction. (Feenstra 1989, 128-152)

The other main strategy, defended recently by Thomas V. Morris, is the “two minds view” (Morris 1986, 63-73, 102-7). This view unfolds in two steps, one defensive, the other constructive. First, Morris claims

that the incoherence charge against the incarnation rests on a mistake. The critic assumes that, for example, humans are essentially non-omniscient. But what are the grounds for this assertion? Unless we think that we have some special direct insight into the essential properties of human nature, our grounds are that all of the human beings we have encountered have that property. But this merely suffices to show that the property is *common* to humans, not that it is essential. As Morris points out, it may be universally true that all human beings, for example, were born within ten miles of the surface of the earth, but this does not mean that this is an *essential* property of human beings. An offspring of human parents born on the international space station would still be human. If this is right, the defender of the incarnation can reject the critic's characterization of human nature, and thereby eliminate the conflict between divine attributes and human nature so characterized.

This merely provides a way to fend off the critic, however, without supplying any positive model for how the incarnation should be understood. In the second step, then, Morris proposes that we think about the incarnation as the realization of one person with two minds: a human mind and a divine mind. If possession of a human mind and body is sufficient for something's being a human, then “merging” the divine mind with a human mind and conjoining both to a human body will yield one person with two natures. During his earthly life, Morris proposes, Jesus Christ had two minds, with consciousness centered in the human mind. This human mind had partial access to the contents of the divine mind, while God the Son's divine mind had full access to the corresponding human mind.

The chief difficulty the view faces is the coherence of holding that a single person can possess two distinct minds. Does this view propose an Incarnate Christ with multiple personality disorder? Morris claims that this objection lacks merit. In fact, contemporary psychology seems to provide resources which support the viability of such a model. As Morris points out elsewhere, the human mind is typically characterized as a system of somewhat autonomous subsystems. The normal human mind, for example, includes the workings of the conscious mind, the seat of awareness, and the unconscious mind. Morris proposes that similar sorts of relations can be supposed to obtain between the divine and human mind of Christ.

4. Atonement

Traditional Christianity holds that sin separates human creatures from God, and that reconciliation can occur in virtue of something that happens through the incarnation, life, death, and resurrection of Jesus Christ. But how are these claims of separation and reconciliation to be understood? The answer to these questions makes up the doctrine of atonement. Throughout the history of Christian theology, a variety of models have been proposed. Most of these models fall into one of four types. *Ransom* theories contend that sin has rendered humans enslaved to the Devil. In order to free his beloved creatures from this enslavement God was required to pay a ransom, and the price was the death of his sinless incarnate Son. *Penal Substitution* models contend that through sin humans have incurred a moral debt which needs to be paid. These views hold that the price to be paid is spiritual death and separation from God. No one man can pay the debt of any other since all men have sinned equally. Thus, God chose to send his incarnate Son, free from original or committed sin, to die on behalf of others, and so satisfy their debt.

Sacrifice models are similar to substitution models, but differ in that they do not think that any moral debt of human creatures can be transferred and satisfied by another. Sacrifice theories acknowledge that wrongdoers incur an obligation to “make things right” with the person wronged. Sometimes this means making restitution. Other times it means undertaking acts of penance which demonstrate the wrongdoer's genuine remorse. Thus, if I, in a fit of anger, throw a brick through the window of your house, I might come to seek forgiveness. In doing so I agree to fix the broken window (restitution) but might also do something more, such as bring you a gift as way of demonstrating my genuine remorse. This latter is the act of penance. However, sometimes restitution and suitable penance cannot be carried out by the wrongdoer himself because restitution or suitable penance is beyond his means. In the case of human sinfulness towards God, this is exactly the case. As a result, God sent Christ to earth, where Christ willingly offered his life as a restitution and penance for the sin of the world. Thus, although human sinful creatures cannot make restitution or penance for their wrongdoing on their own, they can, in their repentance, offer up to God the sacrifice of Christ which was made on their behalf.

Finally, *Moral Exemplar* theories hold that the atonement is secured by moral reform of the sinner. But such moral reform was not fully possible without someone to set the moral example for fallen creatures. Christ became incarnate, on these theories, in order to set this example and thus provide a necessary condition for moral reform and thus restoration of the relationship between creature and Creator.

Ransom theories have no defenders in the recent literature. While each of the remaining theories has defenders, each faces certain key difficulties as well. Substitution theories, for example, require a few central controversial claims. For one, these theories seem to entail that a person can incur an infinite moral debt for a finite amount of earthly wrongdoing. Second, they entail that the moral debt in question cannot simply be forgiven by God, but that it must be settled by full payment. Some have argued that this entails that God does not forgive sin at all. (Stump 1988, 61-5) Forgiveness involves remitting some of the payment owed. On these theories however, the debt is paid in full. Most controversial, however, is the claim that moral debts of the sort in question here are transferable. That is, on this view it seems that the punishment of one can be fairly borne by another. While this might be acceptable in certain cases where monetary fines are involved, many think that it cannot apply to specifically moral debts.

Sacrifice theories do not encounter these difficulties. Instead they, like moral exemplar theories, face difficulties of two main sorts. First, both views seem unable to account for the Biblical emphasis on the necessity of Christ's passion to remedy the problems brought forth by sin. It is hard to see why Christ's passion plays any essential role in establishing him as moral exemplar. Further, it is hard to see why Christ's death would provide a suitable sacrifice. Why would it not suffice for Christ to dwell among us and live a perfect human life, resisting all earthly temptation? Second, both views seem unable to account for the necessity of the *horrible nature* of Christ's death on the cross. The reason for this is that both hold that God either could or does forgive the sin of creatures without such grave sacrifices being offered. As a result, one is left to wonder why a solution which does not involve such horrific suffering is preferred to simple forgiveness. This is especially problematic for the moral exemplar theories, which lay almost exclusive emphasis on the importance of Christ's moral example during his life and on the centrality of creaturely moral reform for reconciliation with God.

Defenses of substitution models seem to be on the wane in recent literature, with sacrifice and exemplar theories becoming more widely defended. Can the substitution models overcome the difficulties posed for it above? Some have defended substitution models according to which punishment is a fitting response to human sin, and yet also such that it might nonetheless be fairly borne by a surrogate, in this case, the perfect Christ. Stephen Porter, for example, argues that our moral intuitions generally incline us to view punishment of a surrogate as a bad thing, and that some case needs to be made for its permissibility in this instance (Porter 2001). In run of the mill cases of punishment, the good reasons for punishment (such as reform of the wrongdoer, making reparation, deterrence, and so forth) usually weigh in favor of *not* transferring the punishment to a surrogate. But here, Porter argues, the good reasons for punishing human sinners are not undercut, and that, in fact, there are outweighing reasons for allowing Christ to bear the punishment due human sinners.

Specifically, Porter claims that the goods that come from God's punishment of sin (namely, reparation, manifesting an objective correction to distorted human values, and moral education/reform) justify the punishment. What is more, Porter claims, these ends are more fittingly served through the suffering of Christ on our behalf. The reasons for this are two-fold. First, were we to bear the punishment directly, it might further serve to alienate us from God. Second, the gravity of human sin against an infinite God cannot be suitably expressed by punishment of merely finite humans. Punishment of an infinite God-man better expresses the seriousness of sin.

In Porter's account we have an attempt to respond to the three objections raised earlier against substitution views. First, the (infinite) severity of the punishment is required in order to adequately express the gravity of human sin against an infinite and perfect God. Concerning the second objection (namely, that paying the full price of sin means that there is no forgiveness on God's part), Porter can reply that the objection is simply misguided. God can forgive without any punishment being exacted. However, certain goods arise as a result of punishment being meted out, and God thus metes out punishment suitable for securing those goods. The third difficulty (i.e., the non-transferrability of moral debts) initially seemed to be the most formidable of the three. Porter argues, however, that as long as (a) offender, offended, and surrogate are willing participants, and (b) the goods of punishing can be secured through the punishment of the surrogate, then substitution is permissible, perhaps even preferable. The reason it is permissible, however, is not because the moral debt is “transferred” from sinner to Christ (as the objection assumes) but simply because punishing wrong is a good and punishing a surrogate can equally or better serve the aims of punishing.

Thomas of Erfurt

Thomas of Erfurt was the most influential member of a group of later medieval philosophers known as the speculative grammarians or *Modistae* (Modists), after the central place they assigned to the *modi significandi* (modes of signification) of a word in the analysis of human discourse. The notion that a word, once it has been imposed to signify, carries with it all of its syntactical modes, or possible combinations with other words, had been around since the 12th century. What the *Modistae* did was to explain the origins of the *modi significandi* in terms of parallel theories of *modi intelligendi* (modes of understanding) and *modi essendi* (modes of being). The result was a curious amalgam of philosophy, grammar, and linguistics. Thomas of Erfurt's *De modis significandi* became the standard Modist textbook in the 14th century, though it enjoyed even greater fame later thanks to its misidentification as a work of Duns Scotus. The text was eventually printed as part of Scotus's *Opera Omnia*, where it was read and commented upon by later figures such as Charles S. Peirce and Martin Heidegger, whose 1916 doctoral thesis, *Die Kategorien- und Bedeutungslehre des Duns Scotus*, should have been entitled, *Die Kategorienlehre des Duns Scotus und die Bedeutungslehre des Thomas von Erfurt*.

1. Life

Almost nothing is known about the life of Thomas of Erfurt except that he was active as a teacher and philosopher in the first quarter of the 14th century.[1] Presumably, he came from the city of Erfurt in present-day Germany. His work shows the influence of the Parisian Arts Masters Radulphus Brito (ca. 1270-1320) and Siger of Courtrai (ca. 1280-1341), which suggests that he was educated and perhaps also taught at the University of Paris.[2] Later documents associate him with the school of St. Severus and the *Schottenkloster* of St. Jacob at Erfurt.[3] His most famous grammatical text, *De modi significandi* (On the

Modes of Signifying) was known by 1310 and was already being commented upon by 1324. It is possible that he returned to Paris a number of times over the course of his academic career, although there are no records to attest to this.

Some copies of *De modi significandi* attribute the work to an early 14th-century English cleric named Thomas of Occam, but scholars have been skeptical about this because it occurs in just a handful 15th-century manuscripts.[4] The vast majority of the manuscript evidence, and all of the earliest witnesses, refer to its author as Thomas of Erfurt.

2. Writings

Six works have been attributed to Thomas of Erfurt. In addition to the aforementioned grammatical treatise, whose full title is *Tractatus de modis significandi seu Grammatica speculativa* (ed. Bursill-Hall 1972),[5] there are four short *expositiones*, or literal commentaries: on Porphyry's *Isagoge*, Aristotle's *Categories*, Aristotle's *De interpretatione*, and the anonymous *Liber sex principiorum* (Book of Six Principles). Finally, there is a very brief work of mnemonic verses used to teach grammar to schoolboys, *Commentarius in carmen 'Fundamentum puerorum'* (ed. Gansiniec 1960), although its editor believes that it is actually an anonymous abridgement of *De modis significandi*. In any case, Thomas's entire reputation derives from *De modis significandi*, which is the only one of his works to have been studied in any detail.

De modis significandi proved to be so popular that it became the standard (and later, the representative) text for the Modist tradition (see next section). It exists in over forty 14th- and 15th-century manuscripts. A printed edition appeared in the late 15th century that was reprinted an incredible 11 times before its 'definitive' reprinting in Luke Wadding's 1639 edition of the complete works of Duns Scotus.[6]

3. Modism

Thomas of Erfurt belonged to an interesting though somewhat obscure group of late 13th- and early 14th-century philosophers known as the speculative grammarians or *Modistae*. The term 'speculative grammarian' is ambiguous because it is also used by historians of medieval philosophy to refer to 12th-century Parisian grammar masters such as William of Conches, Peter Helias, and Ralph of Beauvais, who systematically revised the ancient grammars of Donatus and Priscian -- textbooks which had been used to teach Latin to schoolboys -- in order to produce a universal semantics.[7] The two groups are related, as it turns out, since the latter-day grammarians adopted many of the theories as well as the universalizing tendencies of their 12th-century predecessors. Foremost among them was the theory of the *modi significandi*, or modes of signifying. The term '*Modistae*' or 'Modist' properly refers to the later group.

There was already a grammatical concept of the *modi significandi* by the time the first *Modistae*, Martin of Dacia and Boethius of Dacia, appeared in Paris sometime before 1270.[8] Originally, the idea referred

to the different ways in which a word or expression (*dictio*) is able to signify something. Words themselves are the product of a primary act of imposition by which a particular utterance is connected with some thing or property of a thing, the utterance providing the matter, which in turn is said to be 'informed' by the act of imposition. The word acquires its *modi significandi* through a second act of imposition encoding all of the general syntactic roles it can play in connection with other words and expressions, i.e., the various parts of speech it can fulfill (e.g., noun, verb, adverb) and the grammatical forms of these parts (e.g., the gender, number, and case of nouns; the tense and mood of verbs). These modes are said to cause the various lexical forms exhibited by the word in spoken and written languages. Thus, Latin uses the word 'canis' to signify what English speakers mean by 'dog', but the same modes of signifying determine their function as singular and as nouns.[9] We might think of *modi significandi* metaphorically as hooks or fasteners on a word because they reflect its potential for combination with other words in propositions and other grammatically well-formed constructions.

It is easy to see how such an account of meaning could lead to a *bona fide* theory of grammar, what Jan Pinborg has called "the first systematic syntax developed in western linguistics".[10] Indeed, speculative grammarians of both periods have attracted the attention of linguists and philosophers alike.[11] But the stakes were higher for the *Modistae* because the influx of Aristotle's writings on metaphysics and natural philosophy in the late 12th and early 13th centuries forced everyone to think in terms of a new paradigm of knowledge. Could grammar be conceived as the science of language (*scientia sermocinalis*)? The question here was whether grammar could count as an Aristotelian speculative science, i.e., whether it is demonstrative in the sense of being a knowledge-producing activity ordained by a single subject whose principles are universal and necessary.[12] Concerns of this sort clearly underlie Boethius of Dacia's appraisal of traditional grammar:

> subjects in which a demonstrative mode of knowing is possible are seldom taught in a demonstrative way, but descriptively [*sed modo narrativo*] … That is why Priscian states many conclusions for which he offers no reasons, but merely the authority of ancient grammarians. Accordingly, he does not teach, for only those who offer reasons for what they say are teachers.[13]

Thomas of Erfurt indicates in the opening lines of *De modis significativis* that he aims to be one of these teachers:

> *The rationale of the method*. Since in all science, to understand and to know come about from the knowledge of principles, as is written in I *Physics*, text comment 1, therefore, wishing to have knowledge of the science of grammar, it is primarily necessary for us to dwell upon all of its primary *per se* principles of which modes are the modes of signifying. But before knowledge is sought after in the particulars, there are certain things to be set out in advance in general, without which it is not possible to have the fullest understanding of them. (*DMS*, Preamble; Bursill-Hall: 1)

For *Modistae* such as Boethius of Dacia and Thomas of Erfurt, the proper subject of grammar is well-

formed, significant speech (*sermo congrue significativus*), the principles of which are expressed in the *modi significandi*.

But this is where things get interesting, for the *Modistae* also understood the theory of the *modi significandi* to involve claims about the nature of thought and reality. The problem with Priscian, as 12th-century grammarians had pointed out, is that he said nothing about what causes the different parts of speech. Hence the need for a theory of the *modi significandi*. But the *Modistae* saw that this could only be part of the answer, for grammar is a linguistic phenomenon, and linguistic phenomena must have a cause within the natural order of things. Therefore, to complete the explanation, they argued that the formal structure of the *modi significandi* owes its existence to *modi intelligendi*, or modes of understanding, which in turn are caused by *modi essendi*, or the modes of being a thing can exhibit outside the mind.

The heart of the Modist project is the assumption that there is a triadic or parallel relationship between word, concept, and thing. Meaning is based proximately on understanding but ultimately on being. According to Thomas of Erfurt:

> *Every mode of signifying is from some property of the thing*. Concerning the second thing to be noted, that since such notions or modes of signifying are not fictions, it must be that every mode of signifying radically originates from some property of the thing. This is plain thus: since the intellect, in order to signify, imposes the voice under some mode of signifying, it considers the property itself of the thing from which it originally drew the mode of signifying; this is because the intellect, since it is a passive power indeterminate of itself, does not advance to a determinate act unless it is determined from another source. Whence since it imposes the voice in order to signify under the determinate mode of signifying, it is necessarily moved by a determinate property of the thing; therefore some property of a thing, or mode of being of a thing, corresponds to any mode of signifying. (*DMS*, 2.4; Bursill-Hall: 3)

Note the phrase, “since such notions or modes of signifying are not fictions.” The *modi significandi* could not play any causal role in determining the parts of speech, nor the corresponding *modi intelligendi* in determining the *modi significandi*, nor the *modi essendi* in determining the *modi intelligendi*, unless they all actually exist. Here the *Modistae* drew on the Aristotelian idea that although spoken sounds and written marks differ from language to language, “what these are in the first place signs of - affections of the soul - are the same for all; and what these affections are likenesses of - actual things - are also the same” (*De interpretatione* 1.16a3-9).[14] Likewise, the ordering of the modes was intended to replicate the ordering of disciplines in Aristotelian speculative science: just as psychology, the study of moving things *qua* animate, is subordinate to physics, the study of things *qua* moving, and physics is subordinate to metaphysics, the study of things *qua* existing, so the principles of grammar (*modi significandi*) are derived from mental acts of signifying (*modi intelligendi*), which reflect the way things actually are (*modi essendi*).

Tidy conceptual schemes tend to become less so when confronted with the facts. The *Modistae* spent a lot of time trying to explain recalcitrant linguistic data. After sketching the origins of the *modi significandi* in the first chapters of his treatise, Thomas immediately considers a few objections: how can ‘goddess [*dea*]’ be signified with a feminine noun, which connotes passivity? Answer: a mode of signifying need not always be drawn from the thing signified, for sometimes it “can be taken from the property of the thing of another utterance;” thus, when we say ‘in God’, we do not mean to attribute a passive property to God, who suffers not, but only to “imagine him as if being affected by our prayers.” When we use a passive or feminine mode of signifying in relation to God, what we are really doing is signifying our own passive or feminine conception of some *other* thing that *is* a genuine recipient, i.e., something that does correspond to a determinate mode of being *qua* recipient, and then imposing the same word to signify God. In the same way, we impose names on things we cannot sense via the properties of sensible things, thereby attributing “active modes of signifying to their names” (*DMS* 2.5; Bursill-Hall: 4).

But what about words signifying fictions, such as ‘chimera’, or privations, such as ‘blindness’? These do not correspond to any mode of being, active or passive, since they signify nothing (i.e., no thing). According to Thomas, the active modes of signifying chimeras “are taken from the parts from which we imagine a chimera to be composed, which [fiction] we imagine from the head of a lion, the tail of a dragon, etc.” (*DMS* 2.5; Bursill-Hall: 4) Names of privations, on the other hand, “designate the modes of understanding of privations, which are their modes of being, through their own active modes of signifying about privations”. The idea here is that ‘blindness’ corresponds to our positive concept of sight *qua* absent, which enjoys a positive *modus essendi* in our intellects. Thus, “although privations are not positive beings outside the soul, they are nevertheless positive beings in the soul … and since the understanding of them is their being, therefore, their mode of understanding would be their mode of being” (*DMS* 2.6; Bursill-Hall: 4). Blindness outside the soul cannot cause any conception of itself *per se*, since blindness *per se* does not exist, and what does not exist cannot be the cause of anything. Accordingly, when we say, ‘Homer was a blind man,’ the word ‘blind’ actively signifies the passive mode of understanding something as being without sight, and owes its semantic function to the way its corresponding concept is understood. In the case of concepts that are neither fictions nor privations, these modes of understanding are further determined by their corresponding modes of being, i.e., by actual substances and properties outside the soul.

For the *Modistae*, then, the words ‘chimera’ and ‘horse’ differ, but only in terms of the complexity of their underlying modes. Thomas follows Siger of Courtrai in distinguishing between active and passive *modi significandi*/*modi intelligendi* to explain the difference between the act of signifying/understanding (materially construed as a property of the utterance/concept) and the object signified/understood (materially construed as a property of the thing signified/understood). The fact that nothing answers to the name ‘chimera’ simply does not matter. Modism was a theory about meaning (*significatio*) of a word as opposed to its reference (*suppositio*), and reference was regarded as something determined by the logicians. Besides, if grammatical truths are universal and necessary -- i.e., if there really is a science of grammar -- then they cannot be altered by the fact that there are no chimeras. It is the assumption that some palpable phenomenon must underlie every grammatical truth, causing it to be the way it is, which guides Thomas’s discussion in the remainder of the treatise, which soon moves on to more practical

matters such as the different parts of speech (‘*Etymologia*’) and their syntax (‘*Diasynthetica*’). Included in the latter are the concepts of *constructio* (the syntactic joining of one word to another), *congruitas* (the proper formation of such constructions), and *perfectio* (the proper formation of complete expressions).

Modist explanations of semantic phenomena were extremely complicated. Indeed, if we consider the manifold ways in which a word can be a signifier together with its potential for combination with other words in expressions, there could be infinitely many *modi significandi* -- a proliferation of modes repeated all over again at the level of *modi intelligendi*. Philosophers today think of Meinong’s theory of objects as a paradigm case of ontological incontinence. These philosophers have never met the *Modistae*, who would make even Meinong seem parsimonious. But in a way this is unfair, of course, since the *Modistae* were not ontologists and had no interest in the metaphysical consequences of their theories. They were first and foremost concerned with the phenomenon of linguistic meaning, and invoked whatever entities they felt could best explain what they observed.

Thomas’s *De modis significandi* was the last work to develop Modist doctrine to any significant degree.[15] Its clarity and relative brevity led to its adoption as the standard Modist text in medieval universities, replacing the earlier *Modi significandi* of Martin of Dacia. But by 1330 and for reasons that remain unclear, Modism had completely disappeared from Paris, pushed aside by the more powerful and comprehensive approach of the *Summulae de dialectica* of John Buridan (ca. 1300-1361).[16] Modism was never able to overcome certain difficulties, such as its refusal to recognize extra-linguistic context, as a result of which it could not explain how meaning can be communicated via incongruous or imperfect expressions.[17] But the most likely reason for its demise was that it no longer provided satisfying explanations of the phenomena it was supposed to explain. The one thing it could do, provide an account for the syntax of Latin grammar, could be achieved more economically by other means. In addition, the theory became absurdly complicated in order to save the phenomena of the *modi significandi*, suggesting that the *modi* finally collapsed under their own weight, like so many Ptolemaic epicycles.

4. Influence

Thomas of Erfurt’s *De modis significandi* has enjoyed more attention than it might otherwise have received thanks to its early misidentification as a work of Duns Scotus.[18] As a result, it was printed along with authentic works on logic in volume 1 of Luke Wadding’s 17th-century edition of the *Opera Omnia* of Duns Scotus (Lyons 1639), and again in the 19th-century reprint of Wadding by Juan-Luis Vivès (Paris 1891).[19] Until very recently, the Wadding-Vivès edition was the definitive source for the works of Duns Scotus, so that anyone consulting it would have associated *De modis significandi* with him.[20] Complicating the story somewhat is the fact that Duns Scotus was influenced by Modism early in his career, though this was probably due to his exposure to Modist authors such as Simon of Faversham and Andrew of Cornwall.[21] It is unlikely that he was influenced by Thomas of Erfurt, because *De modis significandi* did not circulate widely until after Scotus's death.

One of the many later figures to have unwittingly admired Thomas was the American philosopher,

Charles Sanders Peirce (1839-1914), who regarded Duns Scotus as a fellow traveler in metaphysics and whose own semiotic theory resembles the Modist program in certain respects.[22] Peirce quotes *verbatim* the first six chapters of *De modis significandis* in an 1869 lecture comparing the views of (what he took to be) Duns Scotus and William of Ockham on names and signification. But the lecture is introductory in character, leaving it uncertain whether Peirce fully appreciated what was at stake in Modistic grammar, rather than viewing it, say, as some sort of linguistic addendum to Scotus's metaphysics.[23]

Another figure so influenced was Martin Heidegger, whose *Habilitationsschrift* was published in 1916 under the title, *Die Kategorien- und Bedeutungslehre des Duns Scotus*. This book has not been much studied by Heidegger scholars, which is a pity because it is more about Heidegger's own project of advancing the Husserlian notion of *a priori* grammar than a work of philosophical exposition and interpretation. In what now seems a classic understatement, the historian of medieval philosophy Martin Grabmann wrote of this book in 1926, "Martin Heidegger has demonstrated the continuity of the *Grammatica speculativa* hitherto attributed to Duns Scotus with the terminology and overall intellectual outlook of Husserl, so that the structure and distinctiveness of the medieval original is somewhat obscured".[24] In his defense, Heidegger never pretends to be doing history of philosophy in *Die Kategorien- und Bedeutungslehre des Duns Scotus*. On the contrary, he states at the beginning of Part II that he is mostly interested in exploring the implications of *De modis significandi* for the broader theory of meaning, and that he is following scholarly consensus in attributing it to Duns Scotus.[25]

In 1922, however, Grabmann conclusively demonstrated that it was Thomas of Erfurt who wrote *De modis significandi*, not Duns Scotus.[26] So the claim that Heidegger wrote his *Habilitationsschrift* on Duns Scotus is only partly true. The first half, *die Kategorienlehre*, is correctly addressed to Duns Scotus's theory of the categories as developed in his authentic commentaries on Porphyry's *Isagoge*, and Aristotle's *Categories* and *De sophisticis elenchis*. But the second half, *die Bedeutungslehre*, is based almost entirely on Thomas of Erfurt.[27]

For more recent influence, we need look no further than Jacques Derrida, who mentions Thomas (this time dressed as himself) in connection with the old Peircean idea that logic is a branch of semiotics: "As in Husserl (but the analogy, although it is most thought-provoking, would stop there and one must apply it carefully), the lowest level, the foundation of the possibility of logic (or semiotics) corresponds to the project of the *Grammatica speculativa* of Thomas d'Erfurt, falsely attributed to Duns Scotus".[28] What impresses Derrida is not so much the reduction of logic to grammar as the deconstructive potential of Husserl's phenomenology of signs. The idea of deconstructing the science of language would have struck Thomas as absurd, of course, though he probably would have felt some affinity with the highly variegated notion of the sign in modern semiotics.

Notes to Erfurt

Notes

1. The factual information in this section and the next has been gathered from Lorenz 1989, the definitive source for Thomas of Erfurt's life and writings.

2. Stephan Grotz comments on the remarkable similarities between the commentaries of Siger and Thomas on Porphyry's *Isagoge* and Aristotle's *Categories* (1998: vii, n. 1). Likewise, Jan Pinborg notes that "long passages of the *Grammatica speculativa* [i.e. *De modis significandi*] are simply taken over from Radulphus Brito" (Pinborg 1974: 372; see also Pinborg 1967).

3. *Schottenklosteren* (lit. 'Scottish cloisters') were monasteries founded by Scottish and Irish Benedictine monks in continental Europe beginning in the 8th century.

4. See Pinborg 1967: 132 and Lorenz 1989: 312-13.

5. Bursill-Hall's edition unfortunately carries over a number of corrupt readings from the text of this work in Wadding 1639. For a list of corrected readings, see Pinborg 1974.

6. See Lorenz 1989: 317-24.

7. See Pinborg 1982 and especially Fredborg 1988. This earlier movement culminated in the *Summa super Priscianum* of Peter Helias (ca. 1100-1166), which is also the first example of the genre later made famous by Thomas Aquinas, in his theological *summae*.

8. Modism originated in Paris and was for the most part a Parisian phenomenon, although Modist philosophers later came to teach in England and (of course) Erfurt. For the former, see Robert Andrews: 1999, "Andrew of Cornwall and the Reception of Modism in England," in *Medieval Analyses in Language and Cognition*, Acts of the Symposium, 'The Copenhagen School of Medieval Philosophy', January 10-13, 1996, ed. Sten Ebbesen and Russell L. Friedman, Royal Danish Academy of Sciences and Letters - C. A. Reitzels Forlag, Copenhagen.

9. Of course, not all of the possible *modi significandi* of a word will be realized in all languages. In Latin, 'canis' is masculine, but English omits the modus of gender as a means of distinguishing nouns.

10. Pinborg 1982: 260. Karin Margareta Fredborg (1980) has shown that virtually all 12th-century

authors accepted the idea of a universal grammar.

11.See, e.g., Kelly 1971. For a linguistic account of Modism, see Bursill-Hall 1971 and Robins 1997: 79-109. A more details study can be found in Michael A. Covington: 1984, *Syntactic Theory in the High Middle Ages: Modistic Models of Sentence Structure*, Cambridge University Press, London-New York.

12. More than anything else, it was the search for properly Aristotelian foundations for grammar that led to the eclipse of the 12th-century notion of *grammatica universalis* and its gradual replacement by the full-blown *grammatica speculativa*. See Kneepkens 1995: 247-8.

13. Boethius of Dacia, *Modi Significandi*, Q. 9; Pinborg, Roos, and Jensen 1969: 39, ll. 24-33.

14. Aristotle, *De interpretatione* 1.16a3-9, tr. J. L. Ackrill in Jonathan Barnes (ed.): 1984, *The Complete Works of Aristotle*, vol. 1, Bollingen Series LXXI.2, Princeton University Press, Princeton NJ, 25.

15. For a discussion of developments among "second generation" *Modistae* such as Thomas of Erfurt, see Marmo 1995.

16. 1330 is regarded as the *terminus ad quem* of Modism because in that year, the Averroist master John Aurifaber delivered a scathing attack at the University of Erfurt on the doctrine of the *modi significandi* from which it never fully recovered. But by then the doctrine was already in retreat at Paris, where it had suffered a similar fate at the hands of another Averroist, John of Jandun (see Pinborg 1967: 195-209; 1982: 267-8). The most famous critique of modism -- called, appropriately enough, the *Destructiones modorum significandi* -- was composed nearly half a century later by an unknown Parisian author, once believed to have been Peter d'Ailly (Kaczmarek 1994). Also appearing in the third quarter of the 14th century was the *Quaestiones super secundam partem Doctrinalis* of a certain Master Marsilius (= Marsilius of Inghen?), who seems to have been acquainted with the *Destructiones*. Modism found a few isolated advocates in later centuries, but never again emerged into the semantic mainstream. For discussion of the Erfurt and Paris responses to Modism, see Biard 1989: 242-88.

17. On these points, see Pinborg 1982 and Marmo 1995.

18. Grabmann has found evidence that the misidentification occurred as early as the first half of the 15th century (1926: 116-25). And Duns Scotus is identified as its author in one of the earliest (1491) printed editions (Lorenz 1989: 321ff.).

19. A separate edition of the Wadding version of *De modis significandi* was printed in Garcia 1902.

20. The Wadding-Vivès edition has been made obsolete for many of Duns Scotus's works by the new critical edition (in progress) of his *Opera Omnia*, which, unlike its predecessors, is being prepared according to modern editorial principles. His authentic commentaries on Porphyry's *Isagoge* and

Aristotle's *Categories* have now appeared as Volume I of his *Opera Philosophica* (St. Bonaventure, NY: The Franciscan Institute, 1999), with his commentaries on Aristotle's *Sophistical Refutations* and *On Interpretation* (both versions) slated for Volume II (in press).

21. For discussion, see the editors' introduction to *B. Ioannis Duns Scoti, Quaestiones in Librum Porphyrii Isagoge et Quaestiones super Praedicamenta Aristotelis*, ed. R. Andrews et al., Opera Philosophica I, (St. Bonaventure, NY: The Franciscan Institute, 1999): xxxi-xxxiv.

22. Both, for example, understood logic as belonging to semiotics or the general theory of signs. For discussion, see Maurizio Ferriani, "Peirce's Analysis of the Proposition: Grammatical and Logical Aspects," in D. Buzzetti and M. Ferriani (eds.): 1987, *Speculative Grammar, Universal Grammar and Philosophical Analysis of Language*, John Benjamins, Amsterdam-Philadelphia.

23. Peirce viewed logic as a species of semiotics, but Thomas of Erfurt draws no conclusions at all about logic, which he would have regarded as a separate field of inquiry.

24. Grabmann 1926: "Martin Heidegger hat den Gedankengang der bisher dem Duns Scotus zugeteilten *Grammatica speculativa* mit dem Terminologie und der ganzen geistigen Einstellung Husserls wiedergegeben, so daß das mittelalterliche Original in seiner Eigenart und Struktur etwas zurücktritt" (118).

25. Heidegger 1972: 245-6.

26. See Grabmann 1922. It is noteworthy that there were concerns about the authenticity of Duns Scotus's logic within two centuries of his death. The early 16th-century logician Jacob Naveros found the inconsistencies between these texts and his commentary on the *Sentences* sufficient to doubt whether he had written any logical works at all (see E. J. Ashworth, "Jacobus Naveros (fl. ca. 1533) on the Question: 'Do Spoken Words Signify Concepts or Things?'," in *Logos and Pragma. Essays on the Philosophy of Language in Honour of Professor Gabriel Nuchelmans*, ed. L. M. de Rijk and H. A. G. Braakhuis (Nijmegen: Ingenium, 1987): 204). Modern editors have identified four works as authentic: the commentaries on Aristotle's *Categories*, *On Interpretation* (two different versions), *Sophistical Refutations*, and Porphyry's *Isagoge*.

27. Heidegger does not seem ever to have acknowledged the mistake in print, despite having known Grabmann personally, and despite having a splendid opportunity to set the record straight in his introduction to the 1972 reprint of *Die Kategorien- und Bedeutungslehre des Duns Scotus*. This seems to have precipitated needless confusion about his exact relation to Duns Scotus. For example, in a French translation of this work (Heidegger 1970), there is nary a word to suggest that he might have been commenting on anyone other than Duns Scotus. The translator remarks in the introduction that he was able to benefit on several points from correspondence with Heidegger himself. Evidently, the topic of the authenticity of *De modis significandi* was never raised.

28. Derrida 1976: 48.

The Epsilon Calculus

The epsilon calculus is a logical formalism developed by David Hilbert in the service of his program in the foundations of mathematics. The epsilon operator is a term-forming operator which replaces quantifiers in ordinary predicate logic. Specifically, in the calculus, a term $\varepsilon x\, A$ denotes *some x* satisfying $A(x)$, if there is one. In Hilbert's Program, the epsilon terms play the role of ideal elements; the aim of Hilbert's finitistic consistency proofs is to give a procedure which removes such terms from a formal proof. The procedures by which this is to be carried out are based on Hilbert's epsilon substitution method. The epsilon calculus, however, has applications in other contexts as well. The first general application of the epsilon calculus was in Hilbert's epsilon theorems, which in turn provide the basis for the first correct proof of Herbrand's theorem. More recently, variants of the epsilon operator have been applied in linguistics and linguistic philosophy to deal with anaphoric pronouns.

Overview

By the turn of the century David Hilbert and Henri Poincaré were recognized as the two most important mathematicians of their generation. Hilbert's range of mathematical interests was broad, and included an interest in the foundations of mathematics: his *Foundations of Geometry* was published in 1899, and of the list of questions posed to the International Congress of Mathematicians in 1900, three addressed distinctly foundational issues.

Following the publication of Russell's paradox, Hilbert presented an address to the Third International Congress of Mathematicians in 1904, where, for the first time, he sketched his plan to provide a rigorous foundation for mathematics via syntactic consistency proofs. But he did not return to the subject in earnest until 1917, when he began a series of lectures on the foundations of mathematics with the assistance of Paul Bernays. Although Hilbert was impressed by the work of Russell and Whitehead in their *Principia Mathematica*, he became convinced that the logicist attempt to reduce mathematics to logic could not succeed, due in particular to the non-logical character of their axiom of reducibility. At the same time, he judged the intuitionistic rejection of the law of the excluded middle as unacceptable to mathematics. Therefore, in order to counter concerns raised by the discovery of the logical and set-theoretic paradoxes, a new approach was needed to justify modern mathematical methods.

By the summer of 1920, Hilbert had formulated such an approach. First, modern mathematical methods were to be represented in formal deductive systems. Second, these formal systems were to be proved syntactically consistent, not by exhibiting a model or reducing their consistency to another system, but by a direct metamathematical argument of an explicit, "finitary" character. The epsilon calculus was to provide the first component of this program, while his epsilon substitution method was to provide the second.

The epsilon calculus is, in its most basic form, an extension of first-order predicate logic with an "epsilon operation" that picks out, for any true existential formula, a witness to the existential quantifier. The extension is conservative in the sense that it does not add any new first-order consequences. But, conversely, quantifiers can be defined in terms of the epsilons, so first-order logic can be understood in terms of quantifier-free reasoning involving the epsilon operation. It is this latter feature that makes the calculus convenient for the purpose of proving consistency. Suitable extensions of the epsilon calculus make it possible to embed stronger, quantificational theories of numbers and sets in quantifier-free calculi. Hilbert expected that it would be possible to demonstrate the consistency of such extensions.

The Epsilon Calculus

In his Hamburg lecture in 1921 (1922), Hilbert first presented the idea of using choice functions to deal with the principle of the excluded middle in a formal system for arithmetic. These ideas were developed into the epsilon calculus and the epsilon substitution method in a series of lecture courses between 1921 and 1923, and in Hilbert's (1923). The final presentation of the epsilon-calculus can be found in Wilhelm Ackermann's dissertation (1924).

This section will describe a version of the calculus corresponding to first-order logic, while extensions to first- and second-order arithmetic will be described below.

Let L be a first-order language, which is to say, a list of constant, function, and relation symbols with specified arities. The set of epsilon terms and the set of formulae of L are defined inductively, simultaneously, as follows:

- Each constant of L is a term.
- Each variable is a term.
- If s and t are terms, then $s = t$ is a formula.
- If $s_1, \ldots, s_k$ are terms and F is a k-ary function symbol of L, $F(s_1, \ldots, s_k)$ is a term.
- If $s_1, \ldots, s_k$ are terms and R is a k-ary relation symbol of L, $R(s_1, \ldots, s_k)$ is a formula.
- If A and B are formulae, so are $A \wedge B$, $A \vee B$, $A \rightarrow B$, and $\neg A$.
- If A is a formula and x is a variable, $\varepsilon x\, A$ is a term.

Substitution and the notions of free and bound variable, are defined in the usual way; in particular, the variable x becomes bound in the term $\varepsilon x\, A$. The intended interpretation is that $\varepsilon x\, A$ denotes *some* x satisfying A, if there is one. Thus, the epsilon terms are governed by the following axiom (Hilbert's "transfinite axiom"):

$$A(x) \rightarrow A(\varepsilon x\, A)$$

In addition, the epsilon calculus includes a complete set of axioms governing the classical propositional connectives, and axioms governing the equality symbol. The only rules of the calculus are the following:

- Modus ponens
- Substitution: from $A(x)$, conclude $A(t)$, for any term t.

Earlier forms of the epsilon calculus (such as that presented in (Hilbert 1923)) use a dual form of the epsilon operator, in which $\varepsilon x\, A$ returns a value *falsifying* $A(x)$. The version above was used in Ackermann's dissertation, and has become standard.

Note that the calculus just described is quantifier-free. Quantifiers can be *defined* as follows:

$$\exists x\, A(x) \equiv A(\varepsilon x\, A)$$

$$\forall x\, A(x) \equiv \mathrm{A}(\varepsilon x\, (\neg A))$$

The usual quantifier axioms and rules can be derived from these, so the definitions above serve to embed first-order logic in the epsilon calculus. The converse is, however, not true: not every formula in the epsilon calculus is the image of an ordinary quantified formula under this embedding. Hence, the epsilon calculus is more expressive than the predicate calculus, simply because epsilon term can be combined in more complex ways than quantifiers.

It is worth noting that epsilon terms are nondeterministic, thereby representing a form of the axiom of choice. For example, in a language with constant symbols a and b, $\varepsilon x\, (x = a \vee x = b)$ is either a or b, but the calculus leaves it entirely open as to which is the case. One can add to the calculus a schema of *extensionality*,

$$\forall x\,(A(x) \leftrightarrow B(x)) \rightarrow \varepsilon x\, A = \varepsilon x\, B$$

which asserts that the epsilon operator assigns the same witness to equivalent formulae *A* and *B*. For many applications, however, this additional schema is not necessary.

The Epsilon Theorems

The second volume of Hilbert and Bernays' *Grundlagen der Mathematik* (1939) provides an account of results on the epsilon-calculus that had been proved by that time. This includes a discussion of the first and second epsilon theorems with applications to first-order logic, the epsilon substitution method for arithmetic with open induction, and a development of analysis (that is, second-order arithmetic) with the epsilon calculus.

The first and second epsilon theorems are as follows:

First epsilon theorem: Suppose $\Gamma \cup \{A\}$ is a set of quantifier-free formulae not involving the epsilon symbol. If *A* is derivable from Γ in the epsilon calculus, then *A* is derivable from Γ in quantifier-free predicate logic.

Second epsilon theorem: Suppose $\Gamma \cup \{A\}$ is a set of formulae not involving the epsilon symbol. If *A* is derivable from Γ in the epsilon calculus, then *A* is derivable from Γ in predicate logic.

In the first epsilon theorem, "quantifier-free predicate logic" is intended to include the substitution rule above, so quantifier-free axioms behave like their universal closures. Since the epsilon calculus includes first-order logic, the first epsilon theorem implies that any detour through first-order predicate logic used to derive a quantifier-free theorem from quantifier-free axioms can ultimately be avoided. The second epsilon theorem shows that any detour through the epsilon calculus used to derive a theorem in the language of the predicate calculus from axioms in the language of the predicate calculus can also be avoided.

More generally, the first epsilon theorem establishes that quantifiers and epsilons can always be eliminated from a proof of a quantifier-free formula from other quantifier-free formulae. This is of particular importance for Hilbert's program, since the epsilons play the role of ideal elements in mathematics. If quantifier-free formulae correspond to the "real" part of the mathematical theory, the first epsilon-theorem shows that ideal elements can be eliminated from proofs of real statements, provided the axioms are also real statements.

This idea is made precise in a certain general consistency theorem which Hilbert and Bernays derive from the first epsilon-theorem, which says the following: Let *F* be any formal system which results from the predicate calculus by addition of constant, function, and predicate symbols plus true axioms which are quantifier- and epsilon-free, and suppose the truth of atomic formulae in the new language is

decidable. Then F is consistent in the strong sense that every derivable quantifier- and epsilon-free formula is true. Hilbert and Bernays use this theorem to give a finitistic consistency proof of elementary geometry (1939, Sec 1.4).

The difficulty for giving consistency proofs for arithmetic and analysis consists in extending this result to cases where the axioms also contain ideal elements, i.e., epsilons.

Herbrand's Theorem

Hilbert and Bernays used the methods of the epsilon calculus to establish theorems about first order logic that make no reference to the epsilon calculus itself. One such example is *Herbrand's theorem* . This is often formulated as the statement that if an existential formula

$$\exists x_1 \ldots \exists x_k\, A(x_1,\ldots, x_k)$$

is derivable in first-order predicate logic (without equality), where A is quantifier-free, then there are sequences of terms $t_1^1, \ldots, t_k^1, \ldots, t_1^n, \ldots, t_k^n$, such that

$$\mathrm{A}(t_1^1,\ldots,t_k^1) \vee \ldots \vee A(t_1^n, \ldots, t_k^n)$$

is a tautology. If one is dealing with first-order logic *with* equality, one has to replace "tautology" by "tautological consequence of substitution instances of the equality axioms"; following Shoenfield we will use the term "quasi-tautology" to describe such a formula.

The version of Herbrand's theorem just described follows immediately from the *Extended First Epsilon Theorem* of Hilbert and Bernays. Using methods associated with the proof of the second epsilon theorem, however, Hilbert and Bernays derived a stronger result that, like Herbrand's original formulation, provides more information. To understand the two parts of the theorem below, it helps to consider a particular example. Let A be the formula

$$\exists x_1\, \forall x_2\, \exists x_3\, \forall x_4\, B(x_1, x_2, x_3, x_4)$$

where B is quantifier-free. The negation of A is equivalent to

$$\forall x_1\, \exists x_2\, \forall x_3\, \exists x_4\, \neg B(x_1, x_2, x_3, x_4).$$

By Skolemizing, i.e., using function symbols to witness the existential quantifiers, we obtain

$$\exists f_2, f_4\, \forall x_1, x_3\, \neg B(x_1, f_2(x_1), x_3, f_4(x_1, x_3)).$$

Taking the negation of this, we see that the original formula is "equivalent" to

$$\forall f_2, f_4\ \exists x_1, x_3\ B(x_1, f_2(x_1), x_3, f_4(x_1, x_3)).$$

The first clause of the theorem below, in this particular instance, says that the formula *A* above is derivable in first-order logic if and only if there is a sequence of terms $t_1^1, t_3^1, \ldots, t_1^n, t_3^n$ in the expanded language with f_2 and f_4 such that

$$B(t_1^1, f_2(t_1^1), t_3^1, f_4(t_1^1, t_3^1)) \vee \ldots \vee B(t_1^n, f_2(t_1^n), t_3^n, f_2(t_1^n, t_3^n))$$

is a quasi-tautology.

The second clause of the theorem below, in this particular instance, says that the formula *A* above is derivable in first-order logic if and only if there are sequences of variables $x_2^1, x_4^1, \ldots, x_2^n, x_4^n$ and terms $s_1^1, s_3^1, \ldots, s_1^n, s_3^n$ in the *original language* such that

$$B(s_1^1, x_2^1, s_3^1, x_4^1) \vee \ldots \vee B(s_1^n, x_2^n, s_3^n, x_4^n)$$

is a quasi-tautology, and such that *A* is derivable from this formula using only the quantifier and idempotency rules described below.

More generally, suppose *A* is any prenex formula, of the form

$$\mathbf{Q}_1 x_1 \ldots \mathbf{Q}_n x_n\ \mathrm{B}(x_1, \ldots, x_n),$$

where *B* is quantifier-free. Then *B* is said to be the *matrix* of *A*, and an *instance of B* is obtained by substituting terms in the language of *B* for some of its variables. The *Herbrand normal form* A^{H} of *A* is obtained by

- deleting each universal quantifier, and
- replacing each universally quantified variable x_i by $f_i(x_i^1, \ldots, x_i^{k(i)})$, where $x_i^1, \ldots, x_i^{k(i)}$ are the variables corresponding to the existential quantifiers preceding $\mathbf{Q}_i$ in *A* (in order), and f_i is a new function symbol designated for this role.

When we refer to an *instance* of the matrix of A^{H}, we mean a formula that is obtained by substituting terms in the expanded language in the matrix of A^{H}. We can now state Hilbert and Bernays’s formulation of

Herbrand's theorem. (1) A prenex formula A is derivable in the predicate calculus if and only if there is a disjunction of instances of the matrix of A^{H} which is a quasi-tautology.

(2) A prenex formula A is derivable in the predicate calculus if and only if there is a disjunction $\bigvee_j B_j$ of instances of the matrix of A, such that $\bigvee_j B_j$ is a quasi-tautology, and A is derivable from $\bigvee_j B_j$ using the following rules:

- from $C_1 \vee \ldots \vee C_i(t) \vee \ldots \vee C_m$
  conclude $C_1 \vee \ldots \vee \exists x\, C_i(x) \vee \ldots \vee C_m$ and

- from $C_1 \vee \ldots \vee C_i(x) \vee \ldots \vee C_m$
  conclude $C_1 \vee \ldots \vee \forall x C_i(x) \vee \ldots \vee C_m$ (if x not in C_j for $j \neq i$),

as well as the idempotence of $\vee$ (from $C \vee C \vee D$ conclude $C \vee D$).

Herbrand's theorem can also be obtained by using cut elimination, via Gentzen's "midsequent theorem." However, the proof using the second epsilon theorem has the distinction of being the first complete and correct proof of Herbrand's theorem. Moreover, and this is seldom recognized, whereas the proof based on cut-elimination provides a bound on the length of the Herbrand disjunction only as a function of the cut rank and complexity of the cut formulas in the proof, the length obtained from the proof based on the epsilon calculus provides a bound as a function of the number of applications of the transfinite axiom, and the rank and degree of the epsilon-terms occurring therein. In other words, the length of the Herbrand disjunction depends only on the quantificational complexity of the substitutions involved, and, e.g., not at all on the propositional structure or the length of the proof.

The version of Herbrand's theorem stated at the beginning of this section is essentially the special case of (2) in which the formula A is existential. In light of this special case, (1) is equivalent to the assertion that a formula A is derivable in first-order predicate logic if and only if A^{H} is. The forward direction of this equivalence is much easier to prove; in fact, for any formula A, $A \rightarrow A^{\mathrm{H}}$ is derivable in predicate logic. Proving the reverse direction involves eliminating the additional function symbols in A^{H}, and is much more difficult, especially in the presence of equality. It is here that epsilon methods play a central role.

Given a prenex formula, the *Skolem normal form* A^{S} is defined dually to A^{H}, i.e., by replacing existentially quantified variables by witnessing functions. If Γ is a set of prenex sentences, let Γ^{S} denote the set of their Skolem normal forms. Using the deduction theorem and Herbrand's theorem, it is not hard to show that the following are pairwise equivalent:

- Γ proves A
- Γ proves A^{H}

- Γ^S proves A
- Γ^S proves A^H

The Epsilon Substitution Method and Arithmetic

As noted above, historically, the primary interest in the epsilon calculus was as a means to obtaining consistency proofs. Hilbert's lectures from 1917-1918 already note that one can easily prove the consistency of propositional logic, by taking propositional variables and formulae to range over truth values 0 and 1, and interpreting the logical connectives as the corresponding arithmetic operations. Similarly, one can prove the consistency of predicate logic (or the pure epsilon calculus), by specializing to interpretations where the universe of discourse has a single element. These considerations suggest the following more general program for proving consistency:

- Extend the epsilon calculus in such a way as to represent larger portions of mathematics.
- Show, using finitary methods, that each proof in the extended system has a consistent interpretation.

For example, consider the language of arithmetic, with symbols for 0, 1, +, $\times$, <. Along with quantifier-free axioms defining the basic symbols, one can specify that the epsilon terms $\varepsilon x A(x)$ picks out the least value satisfying A , if there is one, with the following axiom:

$$(*)\ A(x) \rightarrow A(\varepsilon x A(x)) \wedge \varepsilon x A(x) \leq x$$

The result is a system that is strong enough to interpret first-order (Peano) arithmetic. Alternatively, one can take the epsilon symbol to satisfy the following axiom:

$$A(y) \rightarrow A(\varepsilon x A(x)) \wedge \varepsilon x A(x) \neq y + 1.$$

In other words, if there is any witness y satisfying $A(y)$, the epsilon term returns a value whose predecessor does not have the same property. Clearly the epsilon term described by (*) satisfies the alternative axiom; conversely, one can check that given A, a value of $\varepsilon x (\exists z \leq x A(x))$ satisfying the alternative axiom can be used to interpret $\varepsilon x A(x)$ in (*). One can further fix the meaning of the epsilon term with the axiom

$$\varepsilon x A(x) \neq 0 \rightarrow A(\varepsilon x A(x))$$

which requires that if there is no witness to A, the epsilon term return 0. For the discussion below, however, it is most convenient to focus on (*) alone.

Suppose we wish to show that the system above is consistent; in other words, we wish to show that there is no proof of the formula 0 = 1. By pushing all substitutions to the axioms and replacing free variables

by the constant 0, it suffices to show that there is no propositional proof of 0 = 1 from a finite set of closed instances of the axioms. For that, it suffices to show that, given any finite set of closed instances of axioms, one can assign numerical values to terms in such a way that all the axioms are true under the interpretation. Since the arithmetical operations + and $\times$ can be interpreted in the usual way, the only difficulty lies in finding appropriate values to assign to the epsilon terms.

Hilbert's *epsilon substitution method* can be described, roughly, as follows:

- Given a finite set of axioms, start by interpreting all epsilon terms as 0.
- Find an instance of the axiom (*) above that is false under the interpretation. This can only happen if one has a term t such that $A(t)$ is true in the interpretation, but either $A(\varepsilon x\, A(x))$ is false or the value of t is smaller than the value of $\varepsilon x\, A(x)$.
- "Repair" the assignment by assigning to $\varepsilon x\, A(x)$ the value of t, and repeat the process.

A finitistic consistency proof is obtained once it is shown in a finitistically acceptable manner that this process of successive "repairs" terminates. If it does, all critical formulas are true formulas without epsilon-terms.

This basic idea (the "Hilbertsche Ansatz") was set out first by Hilbert in his 1922 talk (1923), and elaborated in lectures in 1922-23. The examples given there, however, only deal with proofs in which all instances of the transfinite axiom correspond to a single epsilon term $\varepsilon x\, A(x)$. The challenge was to extend the approach to more than one epsilon term, to nested epsilon terms, and ultimately to second-order epsilons (in order to obtain a consistency proof not just of arithmetic, but of analysis).

The difficulty in dealing with nested epsilon terms can be described as follows. Suppose one of the axioms in the proof is the transfinite axiom

$$B(y) \to B(\varepsilon y\, B(y))$$

$\varepsilon y\, B(y)$ may, of course, occur in other formulae in the proof, in particular in other transfinite axioms, e.g.,

$$A(x, \varepsilon y\, B(y)) \to A(\varepsilon x\, A(x, \varepsilon y\, B(y)), \varepsilon y\, B(y))$$

So first, it seems necessary to find a correct interpretation for $\varepsilon y\, B(y)$ before we attempt to find one for $\varepsilon x\, A(x, \varepsilon y\, B(y))$. However, there are more complicated patterns in which epsilon terms may occur in a proof. An instance of the axiom, which plays a role in determining the correct interpretation for $\varepsilon y\, B(y)$ might be

$$B(\varepsilon x\, A(x, \varepsilon y\, B(y))) \to B(\varepsilon y\, B(y))$$

If $B(0)$ is false, then in the first round of the procedure $\varepsilon y\, B(y)$ will be interpreted by 0. A subsequent

change of the interpretation of $\varepsilon x\, A(x, 0)$ from 0 to, say, n, will result in an interpretation of this instance as $B(n) \rightarrow B(0)$ which will be false if $B(n)$ is true. So the interpretation of $\varepsilon y\, B(y)$ will have to be corrected to n, which, in turn, might result in the interpretation of $\varepsilon x\, A(x, \varepsilon y\, B(y))$ to no longer be a true formula.

This is just a sketch of the difficulties involved in extending Hilbert's idea to the general case. Ackermann (1924) provided such a generalization using a procedure which "backtracks" whenever a new interpretation at a given stage results in the need to correct an interpretation already found at a previous stage.

Ackermann's procedure applied to a system of second-order arithmetic, in which, however, second order terms were restricted so as to exclude cross-binding of second-order epsilons. This amounts, roughly, to a restriction to arithmetic comprehension as the set-forming principle available (see the discussion at the end of this section). Further difficulties with second-order epsilon terms surfaced, and it quickly became apparent that the proof as it stood was fallacious. However, no one in Hilbert's school realized the extent of the difficulty until 1930, when Gödel announced his incompleteness results. Until then, it was believed that the proof (at least with some modifications introduced by Ackermann, some of which involved ideas from von Neumann's (1927) version of the epsilon substitution method) would go through at least for the first-order part. Hilbert and Bernays (1939) suggest that the methods used only provides a consistency proof for first-order arithmetic with open induction. In 1936, Gerhard Gentzen succeeded in giving a proof of the consistency of first-order arithmetic in a formulation based on predicate logic without the epsilon symbol. This proof uses transfinite induction up to ε_0. Ackermann (1940) was later able to adapt Gentzen's ideas to give a correct consistency proof of first-order arithmetic using the epsilon-substitution method.

Even though Ackermann's attempts at a consistency proof for second-order arithmetic were unsuccessful, they provided a clearer understanding of the use of second-order epsilon terms in the formalization of mathematics. Ackermann used second-order epsilon terms $\varepsilon f\, A(f)$, where f is a function variable. In analogy with the first-order case, $\varepsilon f\, A(f)$ is a function for which $A(f)$ is true, e.g., $\varepsilon f\, (x + f(x) = 2x)$ is the identity function $f(x) = x$. Again in analogy with the first-order case, one can use second-order epsilons to interpret second-order quantifiers. In particular, for any second-order formula $A(x)$ one can find a term $t(x)$ such that

$$A(x) \leftrightarrow t(x) = 1$$

is derivable in the calculus (the formula A may have other free variables, in which case these appear in the term t as well). One can then use this fact to interpret *comprehension* principles. In a language with function symbols, these take the form

$$\exists f\, \forall x\, (A(x) \leftrightarrow f(x) = 1)$$

for an arbitrary formula $A(x)$. Comprehension is more commonly expressed in terms of set variables, in

which case it takes the form

$$\exists Y\, \forall x\, (A(x) \leftrightarrow x \in Y),$$

asserting that every second order formula, with parameters, defines a set.

Analysis, or *second-order arithmetic,* is the extension of first-order arithmetic with the comprehension schema for arbitrary second-order formulae. The theory is *impredicative* in that it allows one to define sets of natural numbers using quantifiers that range over the entire universe of sets, including, implicitly, the set being defined. One can obtain *predicative* fragments of this theory by restricting the type of formulae allowed in the comprehension axiom. For example, the restriction discussed in connection with Ackermann above corresponds to the *arithmetic comprehension schema,* in which formulae do not involve second-order quantifiers. There are various ways of obtaining stronger fragments of analysis that are nonetheless predicatively justified. For example, one obtains *ramified analysis* by associating an ordinal rank to set variables; roughly, in the definition of a set of a given rank, quantifiers range only over sets of lower rank, i.e., those whose definitions are logically prior.

More Recent Developments

In this section we discuss the development of the epsilon-substitution method for obtaining consistency results for strong systems; these results are of a mathematical nature. We cannot, unfortunately, discuss the details of the proofs here but would like to indicate that the epsilon-substitution method did not die with Hilbert's program, and that a significant amount of current research is carried out in epsilon-formalisms.

Gentzen’s consistency proofs for arithmetic launched a field of research known as *ordinal analysis,* and the program of measuring the strength of mathematical theories using ordinal notations is still pursued today. This is particularly relevant to the *extended Hilbert’s program,* where the goal is to justify classical mathematics relative to constructive, or quasi-constructive, systems. Gentzen’s methods of cut-elimination (and extensions to infinitary logic developed by Paul Lorentzen, Petr Novikov, and Kurt Schütte) have, in large part, supplanted epsilon substitution methods in these pursuits. But epsilon calculus methods provide an alternative approach, and there is still active research on ways to extend Hilbert-Ackermann methods to stronger theories. The general pattern remains the same:

1. Embed the theory under investigation in an appropriate epsilon calculus.
2. Describe a process for updating assignments to the epsilon terms.
3. Show that the procedure is normalizing, i.e., given any set of terms, there is a sequence of updates that results in an assignment that satisfies the axioms.

Since the last step guarantees the consistency of the original theory, from a foundational point of view one is interested in the methods used to prove normalization. For example, one obtains an *ordinal*

analysis by assigning ordinal notations to steps in the procedure, in such a way that the value of a notation decreases with each step.

In the 1960's, William Tait extended Ackermann's methods to obtain an ordinal analysis of extensions of arithmetic with principles of transfinite induction. More recently, Grigori Mints, Sergei Tupailo, and Wilfried Buchholz have considered stronger, yet still predicatively justifiable, fragments of analysis, including theories of arithmetic comprehension and a Δ^1_1-comprehension rule. Toshiyasu Arai has extended the epsilon substitution method to theories that allow one to iterate arithmetic comprehension along primitive recursive well orderings. In particular, his work yields ordinal analyses for predicative fragments of analysis involving transfinite hierarchies and transfinite induction.

As this article is being written, some first steps have been taken in using epsilon substitution method in the analysis of *impredicative* theories. See the annotated bibliography below.

A variation on step 3 above involves showing that the normalization procedure is not sensitive to the choice of updates, which is to say, *any* sequence of updates terminates. This is called *strong normalization.* Mints has shown that many of the procedures considered have this stronger property.

In addition to the traditional, foundational branch of proof theory, today there is a good deal of interest in *structural proof theory*, a branch of the subject that focuses on logical deductive calculi and their properties. This research is closely linked with issues relevant to computer science, having to do with automated deduction, functional programming, and computer aided verification. Here, too, Gentzen-style methods tend to dominate (see, e.g., Troelstra-Schwichtenberg (2000)). But the epsilon calculus can also provide valuable insights; cf. for example Mints (2002) or the discussion of Herbrand's theorem above.

Aside from the investigations of the epsilon calculus in proof theory, two applications should be mentioned. One is the use of epsilon notation in Bourbaki's *Theorie des ensembles* (1958). The second, of perhaps greater current interest, is the use of the epsilon-operator in the theorem-proving systems HOL and Isabelle, where the expressive power of epsilon-terms yields significant practical advantages.

Epsilon Operators in Linguistics, Philosophy, and Non-classical Logics

Reading the epsilon operator as an indefinite choice operator ("an x such that A(x)") suggests that it might be a useful tool in the analysis of indefinite and definite noun phrases in formal semantics. The epsilon notation has in fact been so used, and this application has proved useful in particular in dealing with anaphoric reference.

Consider the familiar example

1. Every farmer who owns a donkey beats it.

The generally accepted analysis of this sentence is given by the universal sentence

2. $\forall x\ \forall y\ (Farmer\ (x) \wedge Donkey(y) \wedge Owns(x, y)) \rightarrow Beats(x, y))$

The drawback is that "a donkey" suggest an existential quantifier, and thus the analysis should, somehow, parallel in form the analysis of sentence 3 given by 4:

3. Every farmer who owns a donkey is happy,
4. $\forall x\ (Farmer(x) \wedge \exists y\ (Donkey(y) \wedge Owns(x, y)) \rightarrow Happy(x))$,

but the closest possible formalization,

5. $\forall\ x\ ((Farmer(x) \wedge \exists y\ (Donkey(y) \wedge Owns(x, y)) \rightarrow Beats(x, y))$

contains a free occurrence of y. Evans suggests that since pronouns are referring expressions, they should be analyzed as definite descriptions; and if the pronoun occurs in the consequent of a conditional, the descriptive conditions are determined by the antecedent. This leads to the following E-type analysis of (1):

$$\forall x\ ((Farmer(x) \wedge \exists y\ (Donkey(y) \wedge Owns(x, y)) \rightarrow Beats(x, \iota y\ (\ Donkey(y) \wedge Owns(x, y)))$$

(ιx is the definite description operator). The trouble with this is that on the standard analysis, the definite description carries a uniqueness condition, and so (5) will be false if there is a farmer who owns more than one donkey. A way out of this is to introduce a new operator, whe (whoever, whatever) which works as a generalizing quantor (Neale, 1991):

$$\forall x\ ((Farmer(x) \wedge \exists y\ (Donkey(y) \wedge Owns(x, y)) \rightarrow Beats(x, \text{whe}\ y\ (Donkey(y) \wedge Owns(x, y)))$$

As pointed out by von Heusinger (1994), this suggests that Neale is committed to pronouns being ambiguous between definite descriptions (ι-expressions) and whe-expressions. Heusinger suggests instead to use epsilon operators indexed by choice functions (which depend on the context). According to this approach, the analysis of (1) is

For every choice function i:
$\forall x\ (Farmer(x) \wedge Owns(x, \varepsilon_i y\ Donkey\ (y)) \rightarrow Beats\ (x, \varepsilon_{a*}\ y\ Donkey\ (\text{y}))$

$a*$ is a choice function which depends on i and the antecedent of the conditional: If i is a choice function which selects $\varepsilon_i y\ Donkey\ (y)$ from the set of all donkeys, then $\varepsilon_{a*}\ y\ Donkey\ (y)$ selects from the set of

donkeys owned by x.

This approach to dealing with pronouns using epsilon operators indexed by choice functions enable von Heusinger to deal with a wide variety of circumstances (see Egli and von Heusinger, 1995; von Heusinger, 2000).

Applications of the epsilon-operator in formal semantics, and choice functions in general, have received significant interest in recent years. Von Heusinger and Egli (2000a) list, among others, the following: representations of questions (Reinhart, 1992), specific indefinites (Reinhart 1992; 1997; Winter 1997), E-type pronouns (Hintikka and Kulas 1985; Slater 1986; Chierchia 1992, Egli and von Heusinger 1995) and definite noun phrases (von Heusinger, 1997).

For discussion of the issues and applications of the epsilon operator in linguistics and philosophy of language, see B. H. Slater's article on epsilon calculi (cited in the Other Internet Resources section below), and the collections (available online) edited by von Heusinger *et al.*, listed in the Bibliography.

Another application of epsilon calculus is as a general logic for reasoning about arbitrary objects. Meyer Viol (1995) provides a comparison of the epsilon calculus with Fine's (1985) theory of arbitrary objects. Indeed, the connection is not hard to see. Given the equivalence $\forall x\, A(x) \equiv \mathrm{A}(\varepsilon x\, (\neg A))$, the term $\varepsilon x\, (\neg A)$ is an arbitrary object in the sense that it is an object of which A is true iff A is true generally.

Meyer Viol (1995, 1995a) contain further proof- and model-theoretic studies of the epsilon calculus; specifically intuitionistic epsilon calculi. Here, the epsilon theorems no longer hold, i.e., introduction of epsilon terms produces non-conservative extensions of intuitionistic logic. In fact, as was shown by Bell (1993a, 1993b; Meyer Viol, 1995), addition of the epsilon operator to intuitionistic predicate logic allows us to prove the intuitionistically non-valid principles $\neg A \vee \neg\neg A$ and $(\mathrm{A} \to \mathrm{B}) \vee (\mathrm{A} \to \mathrm{B})$. The full principle of the excluded middle can only be proved if we also add epsilon extensionality.

$$\forall x\, (A(x) \leftrightarrow B(x)) \to \varepsilon x\, A = \varepsilon x\, B$$

This result provides a rigorous justification of Hilbert's original conjecture that the principle of the excluded middle is, in a sense, a special case of the axiom of choice, and that only with epsilon extensionality do we get the full strength of the choice principle.

Other model-theoretic investigations of epsilon operators in intuitionistic logic can be found in DeVidi (1995). For epsilon-operators in many-valued logics, see Mostowski (1963), for modal epsilon calculus, Fitting (1975).

Philosophy for Children

Philosophy typically makes its formal entry into the curriculum at the college level. A growing number of high schools offer some introduction to philosophy, often in special literature courses for college bound students. This suggests that serious philosophical thinking is not for pre-adolescents. Two reasons might be offered for accepting this view. First, philosophical thinking requires a level of cognitive development that, one may believe, is beyond the reach of pre-adolescents. Second, the school curriculum is already crowded; and introducing a subject like philosophy will not only distract students from what they need to learn, it may encourage them to become skeptics rather than learners. However, there are grounds for challenging both of these reasons for resisting philosophy for children. They will be addressed in turn.

---

1. Are Children Capable of Philosophical Thinking?

Jean Piaget's (1933) well-known theory of cognitive development suggests that prior to age 11 or 12, most children are not capable of philosophical thinking. This is because, prior to this time, children are not capable of “thinking about thinking,” the sort of meta-level thinking that characterizes philosophical thinking. This “formal operational” level of cognitive development includes analogical reasoning about relationships, such as: “Bicycle is to handlebars as ship is to rudder, with “steering mechanism” being the similar relationship.” (Goswami, p. xxi). However, there is a growing body of psychological research suggesting that Piaget's account seriously underestimates children's cognitive abilities. (Astington, 1993; Gopnik, et.al.)

Philosopher Gareth Matthews goes further and argues at length that Piaget failed to see the philosophical thinking manifest in the very children he studied. Matthews (1980) provides a number of delightful examples of very young children's philosophical puzzlement. For example:

- TIM (about six years), while busily engaged in licking a pot, asked, “Papa, how can we be sure that everything is not a dream?” (P. 1)
- JORDAN (five years), going to bed at eight one evening, asked, “If I go to bed at eight and get up at seven in the morning, how do I really know that the little hand of the clock has gone around only once? Do I have to stay up all night to watch it? If I look away even for a short time, maybe the small hand will go around twice.” (P. 3)
- ONE DAY John Edgar (four years), who had seen airplanes take off, rise, and gradually disappear into the distance, took his first plane ride. When the plane stopped ascending and the seat-belt sign went out, John Edgar turned to his father and said in a rather relieved but still puzzled, tone of voice, “Things don't really get smaller up here.” (P. 4)

Matthews acquired many of his anecdotes from friends who knew of his interest in the philosophical thinking of children. It is not uncommon for attentive adults to encounter such examples.

However, it might be objected that more than such anecdotes are needed to show that children are capable of serious philosophical thinking. What is needed is evidence that children are capable of *sustained* philosophical discussion. Matthews (1984) provides illustrations of this, too. Meeting with a group of 8-11 year olds, he used the following example to develop a story for discussion:

> Ian (six year old) found to his chagrin that the three children of his parents' friends monopolized the television; they kept him from watching his favorite program. “Mother,” he asked in frustration, “why is it better for three children to be selfish than one?” (Pp. 92-3)

This generated a lively discussion in which children commented on the inconsiderateness of the three visiting children, the desirability of working out a solution that would satisfy all four children, the importance of respecting people's rights, and how one might feel if he or she were in Ian's place. Matthews then posed a possible utilitarian approach: “What about this argument, that if we let the three visitors have their way, three people will be made happy instead of just one?” One reply was that it would not be fair for three people to get what they want at the expense of a fourth. This triggered a discussion of fairness that addressed more specific concerns about the relative ages of the children, whether they are friends, siblings, or strangers—and what types of television programs are involved.

No doubt, part of the explanation of the children’s ability and willingness to carry on an extended discussion of Ian's circumstance is that they have faced similar challenges. Still, the children exhibited a rather sophisticated conceptual grasp of the issues at hand, which is what one might expect from children once they are invited to reflect on their own experiences.

Stories about those roughly their own age can provide opportunities for children to discuss ideas that are most important to them. Consider this example from Matthew Lipman's novel *Lisa* (1983). Harry and his friend Timmy go to a stamp club to trade stamps. Afterward they stop for ice cream cones, but Timmy discovers he has no money. Harry offers to buy him one, and Timmy says he will buy Harry a cone next time. As they are leaving the store, one of their classmates trips Timmy. Timmy then knocks the tripper's books off the table. After running away from the scene, Timmy and Harry talk about what has happened:

> “I couldn't let them get away with it,” Timmy remarked when they saw that they weren't being pursued and could slow down to a walk. “He didn't have to stick his foot out.” Then he added, “Of course, I didn't have to do what I did either. But, like I said before, turnabout is fair play.”
>
> “Somehow," Harry thought, “it isn't quite the same thing.” But he couldn't figure out why. “I don't know,” he said finally to Timmy. “The purpose of your stamp club is to exchange stamps. So when you give someone stamps, you're supposed to give something back. Just like if someone lends me money, I'm supposed to give it back. But if someone pulls a dirty trick on you, should you do the same thing to him? I'm not so sure.”
>
> “But I had to get even,” Timmy protested. “I couldn't let him get away with it, tripping me like that for no reason.”
>
> A bit later they met Lisa and Laura. Harry told the girls what had happened and why he was puzzled. “It reminds me,” remarked Lisa, “of last year when we were learning about how some sentences could be turned around and would stay true, while others, when you turned them around, would become false.”
>
> “Yeah,” Harry agreed, “but there we found a rule. What's the rule here?” Lisa tossed her long hair so that it hung over her right shoulder. “It looks like there are times when it is right to give back what we got and other times when it is wrong. But how do we tell which is which?” (*Lisa*, pp. 23-4)

This passage is an invitation to explore the moral nuances of reciprocity, or “returning in kind.” What might a group of 10-11 year-olds have to say about this? Here is a sampling from a 30 minute discussion of the *Lisa* passage by a group of fifth graders. (Pritchard 1996) Although the group had been discussing philosophical ideas once a week after school for the past several months, this was an impromptu discussion of this passage. With little prompting from the teacher, the students raised and vigorously pursued the following questions:

- What is likely to happen when we retaliate? Will this simply start a long chain of trying to “get things even” that no one (other than perhaps the initiator) wants?
- Can retaliating really “get things even”? Can we even make sense of “getting things even”?

- Is it really right to respond to a wrong by returning in kind? Is this trying to make a right out of two wrongs?
- What alternatives to trying to "get things even" might there be? What would happen if you just ignore someone who is trying to get a rise out of you?
- When is self-defense the best strategy?
- Is there a difference between trying to "get things even" and trying to "teach someone a lesson"?
- How is hitting back different from: a) exchanging goods; b) paying back a debt; c) returning a favor; d) offering a favor; e) not doing someone a favor unless they do one for you?
- Can the Golden Rule help us here? What does the Golden Rule *mean*? Is it a *good* rule?

Thoughtful and insightful discussions like this are not unusual for children who are given the opportunity to have them. This discussion was prompted by a children's novel. However, students' regular classroom materials, works of art, thought experiments, or even the daily newspaper can be used to trigger philosophical discussions of moral concerns.

Even if one concedes that children are quite capable of engaging in extended discussions of *moral* concepts related to their own experiences, what about philosophical ideas less related to their practical affairs? Here is an illustration that begins with logic and ends up in metaphysics.

The true sentence, "All oaks are trees" becomes false when reversed. So does, "All carrots are vegetables." Can we say that *every* true sentence beginning with 'all' becomes false when reversed?

At least as early as the 3rd grade, children easily find exceptions. What about "All tigers are tigers", many will ask. Others may respond that this is a "boring" sentence, offering something like "All rabbits are hares," or "All mothers have children" as alternatives. With relatively little encouragement, they can come up with good definitions of geometric figures and differentiate them from proposed definitions that cannot be reversed. For example, "All squares are rectangles" is true, but it becomes false when reversed. "All squares are rectangles with equal sides," however, can be reversed.

Although the study of logic is traditionally regarded as a part of philosophy, skeptics might not find the reflections of children on rules of logic terribly interesting philosophically. (Of course, some might say this about elementary logic in the college classroom, as well.) It is not that different from basic math and grammar, they might object. Whether or not this is a fair assessment, for many children it is but a short step from logic to metaphysics. Here is an example from a 4th grade class that had just been asked whether true sentences beginning with 'all' always become false when reversed. (Pritchard 1996) reversed. After the usual "All tigers are tigers" and "All rabbits are hares" were suggested, a student asked, "How about 'All answers have questions' and 'All questions have answers'?" Fortunately, the teacher paused to explore this with the class. "Do all answers have questions?" he asked. Of course, replied the students, otherwise we would not say that we have an *answer*.

The teacher continued, "How about the other sentence? Do you think that all questions have answers?" What followed was a flood of responses:

- Student #1: “Is there life in the center of the sun?”
- Student #2: “Even though we can’t go there to find out, the question still has an answer.”
- Student #3: “How many grains of sand are there on earth?”
- Student #4: “There’s definite number even though we don’t know what it is.”
- Student #3: “The wind will blow them all around, and we’ll count some more than once.”
- Student #5: “There are too many to count.”
- Student #6: “How many grains of sand are there on all the planets?”
- Student #7: “How many trees are there on earth?”
- Student #4: “That’s easier than grains of sand. We could count them.”
- Student #7: “By the time you finish counting them, some would have fallen down and others would have started to grow.”
- Student #8: “Did God make time begin?”
- Student #9: “You mean, *if* there is a God, did he make time begin?”
- Student #7: “Does space have limits?”
- Student #5: “Yeah, what would happen if you got to the end of space and tried to put your hand out? If you couldn’t, what would be holding it back on the outside?”
- Student #6: &#!47;Maybe what would hold your hand back is on the inside. There wouldn’t be any outside.”

During the course of discussing these questions, the students seemed to be struggling to move from questions that are difficult, if not impossible, to answer because of our *practical* limitations (e.g., not being certain that a particular grain of sand has not already been counted) to questions that *in principle* are unanswerable. Finally, with a mischievous grin on his face, one of the students asked, “Will time end?” The problem, he explained, is that if time did end, no one would be able later to confirm that this was so.

Here is another illustration of how quickly a discussion of logic can move to a discussion of deep philosophical issues. (Pritchard, 1985) This is a group of 5th graders considering the sentence, “All people are animals.” One of the students offered this as another example of a true sentence that becomes false when reversed. Jeff objected that “All people are animals” is not true. Chip proceeded to develop a taxonomy that relegated people, along with elephants and tigers, under the heading of mammals, mammals under animals, and animals under living things. Jeff continued to object.

> Chip: “Jeff, what are people? Just tell me, what are people? You can’t answer that, can you?”
>
> Jeff: “Yes, I can.”
>
> Chip: “What are you?”
>
> Jeff: “A person.”

Chip: “What’s a person?”

Jeff: “A living somebody.”

Chip: “A living somebody could be a whale.”

Jeff: “I said, *somebody*, not an animal….”

Chip: “You can check every single book out there in the library—well, every one that’s about us….”

Larry: “I want to know why everyone’s getting so huffy about a little subject.”

Rich: “We’re *thinking*! That’s what we’re here for.”

Amy: “Does anyone have an encyclopedia in here so we can look up either animals, mammals, or persons?”

Jeff: “We’re all humans. So, if this Mars guy saw us, he would say, ‘Hey, look, there’s some human beings.’ He wouldn’t say, “Hey, look, there’s some animals down there.’”

Mike: “Martians, if there are any, would say, ‘Hey, look at those weird looking creatures,’ or something like that. They wouldn’t know *what* we are. They don’t know anything about us. [Returning now to Jeff’s original distinction, Mike continues.] If it’s a person, you say, ‘some*body*.’ If it’s an animal you say, ‘some*thing*.’ Somebody is a human body.”

Chip: “There’s living life, okay? Then you branch off from there. You have animals plants, and whatever the other stuff is—you know, molecules and things like that. Now you go to the animals and you branch off—mammals, amphibians, reptiles, and whatever there is. Then you branch off and you have all these special humans. Is that right so far, Jeff?”

Jeff: “Just go on.”

Chip: “Well, I just want to know if you agree so far.”

Jeff: “Just go on. Go on. I’m not going to change my mind. That’s all…. I’m not an animal. I’m a person, and I’m going to stay that way.”

Chip: “You’re a *type* of animal.”

Jeff: “I’m not going to walk up to Dr. Jekyl and say, ‘Hey, change me into an animal’….”

> Amy: “People are a type of animal, like a bird is. That’s different than like an elephant is. A bird’s different than an elephant. And we’re different than a bird. Mike says we don’t call our dog a person or somebody. But someone might be real close to their pet and consider it part of the family.”

The discussion continued for several more minutes. As the group dispersed, one student remarked to another, “If we want to, we could argue for hours!” “For days,” replied the second. Meeting weekly after school in the local public library, this group of children returned the next week with an encyclopedia to settle the matter. After several minutes of discussion, the teacher asked the students if they thought everything in the encyclopedia is true.

> Emily: “Some things we’re not sure of; and the encyclopedia could put down every word about how the solar system was formed, and it would probably say there was big dust that spun around like a top. But we’re not sure about that. And, so, that could be wrong.”

The teacher asked whether, in such cases, the encyclopedia says, “We’re not sure?”

> Mike: “It’ll say ‘hypothesis’—which is a guess.”

> Kurt: “It’ll say we’re not sure yet.”

So, the discussion retained its philosophical vitality. This particular group continued to meet for the entire school year, discussing a wide range of philosophical topics, including: the relationship between the mind and the brain, differences (and similarities) between dreams and reality, knowledge of other minds, self-knowledge, and relationships between evidence and knowledge.

2. Philosophy in a Crowded Curriculum

Given an already crowded curriculum and growing pressure to provide quantifiable evidence of student mastery of the standard subjects of history, literature, math, and science, teachers may question the suitability of adding philosophy to the curriculum. Where is time to be found for the give-and-take of philosophical discussions? Adding philosophy to the mix, they might object, only makes matters worse. Not only is it yet another subject, it is one that is unfamiliar to most teachers, and they may fear that bringing in philosophy, with its continual questioning, will actually interfere with students’ mastery of the subjects already in the curriculum. Given the unsettling nature of much philosophical inquiry, they may feel vulnerable as teachers because they are not confident of their own answers to the questions posed.

Adding to this problem is increasing pressure on teachers to demonstrate that their students are performing at satisfactory levels in the standard subjects. Standardized tests are commonly used as the

measure of student achievement. Marked by definitive, unambiguous questions and answers, these tests do not place a premium on philosophical reflection. Since student performance is typically linked to school funding, this is not something teachers can take lightly, however skeptical they might be about the educational value of preparing their students to perform well on standardized tests.

In response, Matthew Lipman (1991) and others who advocate bring philosophy into the schools emphasize ways in which philosophy can enhance the entire educational experience of students. The aim is more than simply the introduction of one more subject in the schools. By inviting students to reflect on relationships among different areas of inquiry and to make sense of their educational experiences as a whole, philosophy can add to the meaningfulness of students' education as a whole. In addition, philosophy can make important contributions to another area of concern that cuts across the curriculum, critical thinking.

As the Vietnam War escalated in the mid-1960's, so did heated arguments about the wisdom and morality of the war and society's ills in general. Matthew Lipman became dismayed at the quality of argumentation employed by presumably well-educated citizens. Convinced that the teaching of logic should begin long before college, he tried to figure out a way to do this that would stimulate the interest of 10-11 year olds. Leaving Columbia University for Montclair State College, he launched his efforts with his first children's novel, *Harry Stottlemeier's Discovery*(1974). Lipman's concerns about the level of critical thinking in society in general, and the schools in particular, were not his alone. By the 1970's the hue and cry for teaching critical thinking in the schools was, if not clear, at least loud; and it has continued largely unabated to the present.

What is meant by 'critical thinking'? Characterizations range in complexity from Robert Ennis's admirably brief, "reasonable reflective thinking that is focused on deciding what to believe or do" (Ennis) to a complex statement by group of 46 panelists convened by the American Philosophical Association's Committee on Pre-College Philosophy to employ the Delphi Method of striving for consensus:

> We understand critical thinking to be purposeful, self-regulatory judgment which results in interpretation, analysis, evaluation, and inference, as well as explanation of the evidential, conceptual, methodological, criteriological, or contextual considerations upon which that judgment is based…. The ideal critical thinking is habitually inquisitive, well-informed, trustful of reason, open-minded, flexible, fair-minded in evaluation, honest in facing personal biases, prudent in making judgments, willing to reconsider, clear about issues, orderly in complex matters, diligent in seeking relevant information, reasonable in the selection of criteria, focused in inquiry, and persistent in seeking results which are as the subject and the circumstances of inquiry permit. (Facione 1989)

Lipman was a member of this panel, and it is clear that his novels and teacher's manuals all strive to meet these objectives. His briefer depiction of critical thinking is that it involves judgments based on criteria, or reasons. Criteria, he says, can be appraised in terms of "megacriteria" such as reliability,

relevance, strength, coherence, and consistency. (Lipman 1991, p. 119) Critical thinking, he adds, is characterized as “thinking that (1) facilitates judgment because it (2) relies on criteria, (3) is self-correcting, and (4) is sensitive to context.” (Lipman 1991, p. 116)

Picking up on the idea that critical thinking is sensitive to context, critics challenge the notion that critical thinking can be usefully taught independently of specific disciplinary areas. (McPeck) While conceding that there are some generic features of critical thinking that cut across disciplines, they maintain that even these features acquire their meanings only in specific contexts that vary across disciplines (such as history, sociology, biology, chemistry). However, unless the different disciplines ask questions about their own basic assumptions and their relationships to one another, critical thinking within those disciplines will overlook important questions that need attention. Philosophy does ask such questions about other disciplines, as well as about itself.

Lipman’s hope is that philosophy will acquire a central place in the K-12 curriculum, thus enabling students to develop their critical thinking skills through philosophical questioning. At the same time, he claims, philosophy can help students make better sense of their educational experiences. By seeking to develop comprehensive perspectives, philosophy attempts to understand connections. A curriculum that divides students’s education into discrete, self-contained disciplines without encouraging philosophical questions about the nature of those disciplines and their relationships to one another invites a fragmented view of education.

Short of the ambitious program Lipman has in mind for the schools, there are more modest, but worthwhile, ways of bringing philosophical inquiry into the already existing disciplinary structure in the schools. Teachers can invite their students to reflect on philosophical aspects of their subjects of study. At the same time they study history, students can take some time to ask questions about the extent to which historical accounts can be objective—and questions about what ‘objectivity’ might mean, and why it is or is not important to seek it. Similar questions can be asked about the natural and social sciences, including questions about the extent to which science is, or ought to be, “value-free.” (see Goldfarb and Pritchard, in the Other Internet Resources section below). In fact, if room for such questions is not encouraged, one might well ask to what extent critical thinking itself is encouraged.

3. The Institute for the Advancement of Philosophy for Children (IAPC)

The educational movement known as Philosophy for Children got its start in the early 1970s with the publication of Matthew Lipman’s philosophical novel for children, *Harry Stottlemeier’s Discovery*. In 1970 *Harry* made its entry into the Montclair Public Schools in New Jersey. By the mid-70s the Institute for the Advancement of Philosophy for Children (IAPC) was formally in place at Montclair State College (now Montclair State University). The media quickly picked up on reports of significant improvements in the reading and critical thinking skills of middle school children who were involved in IAPC programs. Subsequently, IAPC has produced materials consisting of children’s novels with

accompanying teachers' workbooks for the entire K-12 curriculum. Thousands of children in New Jersey, across the United States, and even around the world have been introduced to IAPC educational programs.

An unassuming 96 page novel for middle-school children, *Harry Stottlemeier's Discovery* features Harry and his 5th grade classmates. Adults occasionally enter in, but the primary philosophical work is the children's. Harry and his friends discover several basic concepts and rules of Aristotelean logic; and they puzzle over questions about the nature of thought, mind, causality, reality, knowledge and belief, right and wrong, and fairness and unfairness. The story does not introduce any of the special vocabulary of philosophy (not even the word 'philosophy' itself makes an appearance). Philosophical inquiry is initiated by the children in the story rather than adults.

"What *is* Harry Stottlemeier's discovery?" *Harry*'s readers might ask. This question is not directly answered. However, one candidate stands out among the many things that Harry discovers in the course of exploring questions about logic, knowledge, reality, and the mind. Harry and his classmates are asked to write a paper on the topic, "The Most Interesting Thing in the World." Entitled *Thinking*, Harry's essay begins:

> To me, the most interesting thing in the whole world is thinking. I know that lots of other things are also very important and wonderful, like electricity, and magnetism and gravitation. But although we understand them, they can't understand us. So thinking must be something very special.

After writing several more paragraphs, Harry puts his paper aside. Later he thinks, "In school, we think about math, and we think about spelling, and we think about grammar. But who every heard of thinking about thinking?" So, he adds one more sentence to his paper: "If we think about electricity, we can understand it better, but when we think about thinking, we seem to understand ourselves better."

Without using the word 'philosophy,' either here or anywhere else in *Harry*, Lipman shows Harry engaged in serious philosophical thought, "thinking about thinking." This, we might say, reveals Harry's discovery of the joys of philosophical thinking. But there is more. Harry also notices that, as interesting and important as thinking about thinking is, it seems to have no special place in school. Finally, although his paper begins in the first person, it quickly moves to 'we' and focuses on what might be accomplished *with others* in the classroom.

One of the more attractive features of Philosophy for Children for many teachers is that it promotes the idea of the classroom as a "community of inquiry" in which students openly and respectfully exchange ideas. Each student is regarded as having the potential to make valuable contributions to the topics under consideration. Students are encouraged to develop good listening skills, responsiveness to what others say, willingness to try to supports one's own ideas with good reasons, and openness to the possibility that one should modify one's beliefs in light of new considerations. In short, the classroom is designed to reinforce the student's potential for *reasonableness*. This involves more than being able to engage in

skillful reasoning. As Laurance J. Splitter and Ann M. Sharp put it (Splitter and Sharp, p. 6):

> Reasonableness is primarily a social disposition: the reasonable person respects others and is prepared to take into account their views and their feelings, to the extent of changing her own mind about issues of significance, and consciously allowing her own perspective to be changed by others. She is, in other words, willing to be reasoned with.

Teachers who look favorably on the idea that the classroom should be a "community of inquiry" nevertheless may resist the idea that *philosophy* should be the centerpiece for discussion. Other subjects, they might contend, lend themselves well to forming the sort of collaborative learning environment that can fairly be called a "community of inquiry." Philosophy for Children advocates need not deny this; however, they can point to the success IAPC has had in showing how well suited philosophy is for promoting the reasonableness of children in a "community of inquiry."

One reason for resistance is that it may be thought that philosophy is, at best, a suitable subject for relatively few students at the pre-college level. Since philosophy traditionally has been taught only at the college level in the United States, it might be thought that it can be suitable for only a small segment of students at pre-college levels—the two percent of students who are classified as "gifted and talented." However, Philosophy for Children programs have shown themselves to be remarkably successful in drawing virtually all students in the classroom together in inquiry. Teachers are often surprised, and pleased, to see many of their most reticent, "underachieving" students actively join in the discussion of philosophical ideas.

Nevertheless, because they lack background in the formal study of philosophy, many teachers are reluctant to encourage the philosophical thinking of their students. Their fears, however, are exaggerated. Familiarity with some of the standard philosophical literature might be desirable, but it is not necessary for bringing Philosophy for Children into the classroom. What is required is the ability to facilitate philosophical discussion. For this, it is much more important that teachers have some philosophical curiosity themselves than a familiarity with academic philosophical literature. Like their students, teachers unfamiliar with the discipline of philosophy may nevertheless have an aptitude for philosophical thinking—or at least a knack for recognizing when others are engaged in philosophical thought.

Facilitating a Philosophy for Children discussion does not mean dominating it; it is important for teachers to allow their students to develop their own ideas. Teachers are not expected to provide, or even have, answers to all the questions. They can share puzzlement with their students, be open to unexpected but suggestive responses to the questions they and their students pose, and take pleasure in observing the exchanges students have with each other. This means shedding the traditional role of teacher as lecturer and answer-giver. Especially for teachers who are uncertain about what this entails, workshops like those offered by IAPC provide a good introduction to the pedagogy of Philosophy for Children.

IAPC's approach has been to prepare a set of novels with accompanying teacher's workbooks, and to prepare teachers to use these materials by conducting intensive workshops that themselves illustrate the

proposed pedagogy. It is emphasized that the teacher's role in the classroom is to facilitate discussion rather than to present philosophical ideas didactically. The novels provide a stimulus for children to come up with their own questions and ideas. Typically, students first read aloud a few paragraphs of a novel. Then they suggest ideas prompted by their reading that they would find it interesting to explore together. The teacher's workbook contains hundreds of thinking exercises and activities that can help the students advance their inquiry. The teacher's aim should be to foster a "community of inquiry" in which students, insofar as possible, themselves initiate discussion and exchange ideas with each other rather than simply respond to teacher prompts. A robust discussion will find students not only stating their own ideas, but also supporting them with reasons and responding to the similarities and differences between their ideas and those of their classmates. This "community of inquiry" is intended to foster a respect for the ideas of others, as well as a respect for one's own.

4. Philosophizing With Others?

Philosophy for Children encourages children to think *for* themselves at the same time that it encourages them to think *with* others. However, philosophy is often viewed as more a matter of solitary reflection, perhaps involving exchanges between a few other solitary thinkers—something to which the "masses" are neither privy nor attracted. Perhaps many would claim that this is philosophy at its best; like physics or mathematics, "philosophy for everyone" is watered down. There is no need for Philosophy for Children to challenge this analogy. In fact, it can turn it in its favor. However esoteric physics and mathematics at their best may be, the schools nevertheless recognize the importance of making these subjects available to all students. Similarly, Philosophy for Children advocates can counter that there should be a place for the entire classroom—including "gifted and talented," "underachieving," and "ordinary" students— pursuing philosophical questions together.

For this to work, it must be possible for children in the classroom to engage in sustained philosophical discussion with others. As already noted, Gareth Matthew's writings provide ample evidence that many children of capable of having interesting, if not profound, philosophical thoughts. Less obvious, however, is children's ability to sustain and develop this with others. Anecdotes of young children spontaneously sharing a philosophical thought with an observant adult are not sufficient. Matthews' *Dialogues With Children* provides good evidence that children can go well beyond this. Transcripts of lengthy philosophical conversations of children found in Pritchard (1985, 1996) and issues of *Thinking* and *Analytic Teaching* should leave little doubt that children have this ability.

Admittedly, this is quite different from the approach of Jostein Gaarder's popular novel, *Sophie's World*, which introduces young readers to philosophy in a dialectical, but nevertheless didactic manner. (New York: Farrar, Straus and Giroux, 1994) Although Sophie is certainly an apt philosophy student, her older mentor clearly leads the way by introducing Sophie to the *history* of philosophy, which in turn is used to illuminate philosophical questions that confront her. As its subtitle *A Novel About the History of Philosophy* suggests, *Sophie's World* aims as much at acquainting its young (and older) readers with a working familiarity with the *history* of philosophy as at encouraging philosophical reflection itself. Philosophy for Children aims primarily at the latter, however much IAPC materials themselves might

indirectly be informed by the history of philosophy. In any case, IAPC supporters might argue, the mentor/apprentice approach of *Sophie's World* tends to reinforce the idea that philosophy is primarily something passed down from adults rather than, as Gareth Matthews suggests, an important aspect of children's natural curiosity.

5. Philosophy For Children Around The World

In 1985, as a reflection of the rapidly expanding international impact of philosophy for children, educators from around the world established the International Council for Philosophical Inquiry with Children (ICPIC). ICPIC sponsors an international conference every other year, with hosts including Australia, Austria, Brazil, England, Mexico, Spain, and Taiwan. Although retaining strong ties with IAPC, ICPIC members have established their own institutional structures and they have developed centers, associations, and programs independently of IAPC. In North America, there is the North American Association of Community of Inquiry, which meets every other year (years when ICPIC is not meeting). Australia and New Zealand are organized under the Federation of Australasian Philosophy for Children Associations (FAPCA), which meets annually. Philosophy for children endeavors can be found in colleges, universities, and associations in more than 20 countries around the world. (Sasseville)

In addition to IAPC materials, there is a great deal of children's literature with rich enough content to be used to facilitate interesting philosophical discussions. (See Matthews, 1980, 1984, 1994 and his regular contributions to IAPC's journal, *Thinking*.) There is also a growing body of philosophy for children educational materials being developed outside of IAPC. (See, e.g., Cam; DeHaan, MacColl, and McCutcheon; Fisher; Keen; Murris; Sprod, and White.) *Thinking*, *Analytical Teaching*, and *Critical & Creative Thinking* are three longstanding journals that are specifically devoted to the philosophical thinking of children. A new periodical, sponsored by the American Philosophical Association's Pre-College Philosophy Committee, is *Questions: Philosophy for Young People*, which features young people's writings on special philosophical topics. The first issue (Spring 2001) focused on children's rights.

Fortunately, the internet makes it possible to keep up with the latest developments around the world and communicate quickly with other educators interested in Philosophy for Children. See the Other Internet Resources section below for a useful list.

Zeno's Paradoxes

Almost everything that we know about Zeno of Elea is to be found in the opening pages of Plato's *Parmenides*. There we learn that Zeno was nearly 40 years old when Socrates was a young man, say 20. Since Socrates was born in 469 BC we can estimate a birth date for Zeno around 490 BC. Beyond this, really all we know is that he was close to Parmenides (Plato reports the gossip that they were lovers when Zeno was young), and that he wrote a book of paradoxes defending Parmenides' philosophy. Sadly this book has not survived, and what we know of his arguments is second-hand, principally through Aristotle and his commentators (here I have drawn particularly on Simplicius, who, though writing a thousand years after Zeno, apparently possessed at least some of his book). There were apparently 40 'paradoxes of plurality', attempting to show that ontological pluralism -- a belief in the existence of many things rather than only one -- leads to absurd conclusions; of these paradoxes only two definitely survive, though a third argument can probably be attributed to Zeno. Aristotle speaks of a further four arguments against motion (and by extension change generally), all of which he gives and attempts to refute. In addition Aristotle attributes two other paradoxes to Zeno. Sadly again, almost none of these paradoxes are quoted in Zeno's original words by their various commentators, but in paraphrase.

1. Background

Before we look at the paradoxes themselves it will be useful to sketch some of their historical and logical significance. First, Zeno sought to defend Parmenides by attacking his critics. Parmenides rejected pluralism and the reality of any kind of change: for him all was one indivisible, unchanging reality, and any appearances to the contrary were illusions, to be dispelled by reason and revelation. Not surprisingly, this philosophy found many critics, who ridiculed the suggestion; after all it flies in the face of some our most basic beliefs about the world. (Interestingly, general relativity -- particularly quantum general relativity -- arguably provides a novel -- if novelty *is* possible -- argument for the Parmenidean denial of change: Belot and Earman, 2001.) In response to this criticism Zeno did something that may sound obvious, but which had a profound impact on Greek philosophy that is felt to this day: he attempted to show that equal absurdities followed logically from the denial of Parmenides’ views. You think that there are many things? Then you must conclude that everything is both infinitely small and infinitely big! You think that motion is infinitely divisible? Then it follows that nothing moves! (This is what a ‘paradox’ is: a demonstration that a contradiction or absurd consequence follows from apparently reasonable assumptions.)

‘Dialectic’, the technique of arguing for or against a position by careful logical reasoning -- and in particular the technique of arguing against a view by showing that it entails unacceptable consequences -- was a crucial innovation, which has governed philosophical method ever since. In the absence of such a method one can only defend a position by mystical revelation say, or by rhetorical rather than rational appeal, or by force perhaps. And according to Aristotle, Zeno was the inventor of the method (in philosophy of least, for such an approach has been a part of mathematics for even longer). Later philosophers however -- especially Plato and Aristotle -- were far finer exponents of the approach.

As we read the arguments it is crucial to keep this method in mind. They are always directed towards a more-or-less specific target: the views of some person or school. We must bear in mind that the arguments are *ad hominem*, not in the ‘bad sense’ that they attack a person rather than his views but in the ‘good sense’ that they are formulated against a particular philosopher’s assertions. They work by temporarily supposing ‘for argument’s sake’ that those assertions are true, and then arguing that if they are then absurd consequences follow -- that nothing moves for example: they are ‘*reductio ad absurdum*’ arguments. Then, if the argument is logically valid, and the conclusion genuinely unacceptable, the assertions must be false after all. Thus when we look at Zeno’s arguments we must ask two related questions: whom or what position is Zeno attacking, and what exactly is assumed for argument's sake? If we find that Zeno makes hidden assumptions beyond what the position under attack commits one to, then the absurd conclusion can be avoided by denying one of the hidden assumptions, while maintaining the position. Indeed commentators at least since Aristotle have responded to Zeno in this way.

So whom do Zeno's arguments attack? There is a huge literature debating Zeno’s exact historical target.

As we shall discuss briefly below, some say that the target was a technical doctrine of the Pythagoreans, but most today see Zeno as opposing common-sense notions of plurality and motion. I will approach the paradoxes in this spirit, and refer the reader to the literature concerning the interpretive debate.

That said, it is also the majority opinion that -- with certain qualifications -- Zeno's paradoxes reveal some problems that cannot be resolved without the full resources of mathematics as worked out in the Nineteenth century (and perhaps beyond). This is not (necessarily) to say that modern mathematics is required to answer any of the problems that Zeno explicitly wanted to raise; arguably Aristotle and other ancients had replies that would -- or should -- have satisfied Zeno. (Nor yet should we conclude that Zeno's work had any direct influence on the history of mathematics, though surely the kind of worries that he raised did.) However, as mathematics developed, and more thought was given to the paradoxes, new aspects and new difficulties arose from them; these difficulties require modern mathematics for their resolution. These new difficulties arise partly in response to the evolution in our understanding of what mathematical rigor demands: solutions that would satisfy Aristotle's standards of rigor would not satisfy ours. Thus we shall push several of the paradoxes from their common sense formulations to their resolution in modern mathematics. (Another qualification: I will offer resolutions in terms of 'standard' mathematics, but other modern formulations are also capable of dealing with Zeno.)

2. The Paradoxes of Plurality

2.1 The Argument from Denseness

> If there are many, they must be as many as they are and neither more nor less than that. But if they are as many as they are, they would be limited. If there are many, things that are are unlimited. For there are always others between the things that are, and again others between those, and so the things that are are unlimited. (Simplicius(a) *On Aristotle's Physics*, 140.29)

This first argument, given in Zeno's words according to Simplicius, attempts to show that there could not be many things, on pain of contradiction. Assume then that there are many things. First, he says that any collection must contain some definite number of things, neither more nor fewer. But if you have a definite number of things, he further concludes, you must have a finite -- 'limited' -- number of them; he implicitly assumes that to have infinitely many things is not to have any particular number of them. Second, imagine any collection of things arranged in space -- imagine them lined up in one dimension for definiteness. Between and two of them, he claims, is a third; and in between these three elements another two; and another four between these five; and so on without end. Therefore the limited collection is also 'unlimited', which is a contradiction, and hence our original assumption must be false: there are not many things after all. At least, so Zeno's reasoning runs.

But why are there 'always others between the things that are'? (In modern terminology, why must objects always be 'densely' ordered?) Suppose that I had imagined a collection of ten apples lined up;

then there is indeed another apple between the sixth and eighth, but there is none between the seventh and eighth! On the assumption that Zeno is not simply confused, what does he have in mind? There are two possibilities: first, one might hold that for any pair of physical objects (two apples say) to actually be two distinct objects and not just one (a 'double-apple') there must be a third between them, physically separating them, even if it is just air. And one might think that for these three to be distinct, there must be two more objects separating them, and so on (this view presupposes that their being made of different substances is not sufficient to render them distinct). Second, one might hold that any body has parts that can be densely ordered. Of course 1/2s, 1/4s, 1/8s and so on of apples are not dense -- some such parts are adjacent -- but there may be sufficiently small parts -- call them 'point-parts' -- that are. Indeed, if between any two point-parts there lies a finite distance, and if point-parts can be arbitrarily close, then they are dense; a third lies at the half-way point of any two. In particular, familiar geometric points are like this, and hence are dense.

And thus we should read the argument as follows: if you suppose that the world contains many things, then you are faced with a contradiction, for the collection must be both finite and infinite -- finite because it contains a definite number of things, and infinite because they are dense. The assumption that any definite number is finite seems intuitive, but we now know, thanks to the work of Cantor in the Nineteenth century, how to understand infinite numbers in a way that makes them just as definite as finite numbers. One central element of the this theory of the 'transfinite numbers' is a precise definition of when two infinite collections are the same size, and when one is bigger than the other -- with such a definition in hand it is then possible to order the infinite numbers just as the finite numbers are ordered. For example, both the fractions and geometric points in a line are dense, but there are different, definite infinite numbers of them. (See Further Reading below for references to introductions to these mathematical ideas.) Of course, settling the mathematical question of whether infinite numbers can be definite doesn't show that real physical objects actually have geometric point parts, all it shows is that it is a logical possibility.

2.2 The Argument from Finite Size

> … if it should be added to something else that exists, it would not make it any bigger. For if it were of no size and was added, it cannot increase in size. And so it follows immediately that what is added is nothing. But if when it is subtracted, the other thing is no smaller, nor is it increased when it is added, clearly the thing being added or subtracted is nothing. (Simplicius(a) *On Aristotle's Physics*,139.9)
>
> But if it exists, each thing must have some size and thickness, and part of it must be apart from the rest. And the same reasoning holds concerning the part that is in front. For that too will have size and part of it will be in front. Now it is the same thing to say this once and to keep saying it forever. For no such part of it will be last, nor will there be one part not related to another. Therefore, if there are many things, they must be both small and large; so small as not to have size, but so large as to be unlimited. (Simplicius(a) *On Aristotle's Physics*, 141.2)

Once again we have Zeno's own words. According to his conclusion, there are three parts to this argument, but only two survive. The first -- missing -- argument purports to show that if many things exist then they must have no size at all. Second, from this Zeno argues that it follows that they do not exist at all; since the result of joining (or removing) a sizeless object to anything is no change at all, he concludes that the thing added (or removed) is literally nothing. The argument to this point is a self-contained refutation of pluralism, but Zeno goes on to generate a further problem for someone who continues to urge the existence of a plurality. This third part of the argument is rather badly put but it seems to run something like this: suppose there is a plurality, so some spatially extended object exists (after all, he's just argued that inextended things do not exist). Since it is extended, it has two spatially distinct parts (one 'in front' of the other). And the parts exist, so they have extension, and so they also each have two spatially distinct parts; and so on without end. And hence, the final line of argument seems to conclude, the object, if it is extended at all, is infinite in extent.

But what could justify this final step? It doesn't seem that because an object has two parts it must be infinitely big! And neither does it follow from any other of the divisions that Zeno describes here; four, eight, sixteen, or whatever finite parts make a finite whole. Again, surely Zeno is aware of these facts, and so must have something else in mind, presumably the following: he assumes that if the infinite series of divisions he describes were repeated infinitely many times then a definite collection of parts would result. And notice that he doesn't have to assume that anyone could actually carry out the divisions -- there's not enough time and knives aren't sharp enough -- just that an object can be geometrically decomposed into such parts (neither does he assume that these parts are what we would naturally categorize as distinct physical objects like apples, cells, molecules, electrons or so on, but only that they are geometric parts of these objects). Now, if -- as a pluralist might well accept -- such parts exist, it follows from the second part of his argument that they are extended, and, he apparently assumes, an infinite sum of finite parts is infinite.

Here we should note that there are two ways he may be envisioning the result of the infinite division.

First, one could read him as first dividing the object into 1/2s, then one of the 1/2s -- say the second -- into two 1/4s, then one of the 1/4s -- say the second again -- into two 1/8s and so on. In this case the result of the infinite division results in an endless sequence of pieces of size 1/2 the total length, 1/4 the length, 1/8 the length … . And then so the total length is (1/2 + 1/4 + 1/8 + …) of the length, which Zeno concludes is an infinite distance, so that the pluralist is committed to the absurdity that finite bodies are 'so large as to be unlimited'.

What is often pointed out in response is that Zeno gives us no reason to think that the sum is infinite rather than finite. He might have had the intuition that any infinite sum of finite quantities, since it grows endlessly with each new term must be finite, but one might also take this kind of example as showing that some infinite sums are after all finite. Thus, contrary to what he thought, Zeno has not proven that the absurd conclusion follows. However, what is not always appreciated is that the pluralist is not off the hook so easily, for it is not enough just to say that the sum *might* be finite, she must also show that it *is* finite -- otherwise we remain uncertain about the tenability of her position. As an illustration of the

difficulty faced here consider the following: many commentators speak as if it is simply obvious that the infinite sum of the fractions is 1, that there is nothing to infinite summation. But what about the following sum: 1 - 1 + 1 - 1 + 1 - … . Obviously, it seems, the sum can be rewritten (1 -1) + (1 - 1) + … = 0 + 0 + … = 0. Surely this answer seems as intuitive as the sum of fractions. But this sum can also be rewritten 1 - (1 - 1 + 1 - 1 + …) = 1 - 0 -- since we've just shown that the term in parentheses vanishes -- = 1. Relying on intuitions about how to perform infinite sums leads to the conclusion that 1 = 0. Until one can give a theory of infinite sums that can give a satisfactory answer to any problem, one cannot say that Zeno's infinite sum is obviously finite. Such a theory was not fully worked out until the Nineteenth century by Cauchy. (In Cauchy's system 1/2 + 1/4 + … = 1 but 1 - 1 + 1 - … is undefined.)

Second, it could be that Zeno means that the object is divided in half, then both the 1/2s are both divided in half, then the 1/4s are all divided in half and so on. In this case the pieces at any particular stage are all the same finite size, and so one concludes that the result of carrying on the procedure infinitely would be pieces the same size, which if they exist -- according to Zeno -- is greater than zero; but an infinity of equal extended parts is indeed infinitely big.

Actually a little care is needed in drawing this conclusion. The procedure just described involves doubling the number of pieces after every division and so after N divisions there are 2^N pieces. But it turns out that for any natural or infinite number, N, $2^N > N$, and so the number of pieces obtained by the infinity of divisions described is an even larger infinity. This is no problem as we mentioned above, since infinities come in different sizes. The number of times everything is divided in two is said to be 'countably infinite': there is a countable infinity of things in a collection if they can be labeled by the numbers 1, 2, 3, … without remainder on either side. But the number of pieces is 'uncountably infinite', which means that there is no way to label them 1, 2, 3, … without missing some of them -- in fact infinitely many of them. However, Cauchy's definition of an infinite sum only applies to countably infinite series of numbers, and so does not apply to the pieces we are considering. However, we could consider just countably many of them, whose lengths -- since they are all equal and non-zero -- will sum to an infinite length; clearly the length of *all* of the pieces cannot be less than this.

There is however an escape for the pluralist who believes that objects have parts of this kind (which they do if they have parts with the properties of geometric points): she must claim that the parts in fact have no extension, even though they exist. That would block the conclusion that finite objects are infinite, but it seems to push her back to the other horn of Zeno's argument, for how can all these zero length pieces make up a non-zero sized whole? (Note that according to Cauchy 0 + 0 + 0 + … = 0 but this result shows nothing here, for as we saw there are uncountably many pieces to add up -- more than are added in this sum.) We shall postpone this question for the discussion of the next paradox, where it comes up explicitly.

2.3 The Argument from Complete Divisibility

> … whenever a body is by nature divisible through and through, whether by bisection, or generally by any method whatever nothing impossible will have resulted if it has actually

> been divided … . though perhaps nobody in fact could so divide it.
>
> What then will remain? A magnitude? No: that is impossible, since then there will be something not divided, whereas *ex hypothesi* the body was divisible *through and through*. But if it be admitted that neither a body nor a magnitude will remain … the body will *either* consist of points (and its constituents will be without magnitude) *or* it will be absolutely nothing. If the latter, then it might both come-to-be out of nothing and exist as a composite of nothing; and thus presumably the whole body will be nothing but an appearance. But if it consists of points, it will not possess any magnitude. (Aristotle *On Generation and Corruption*, 316a19)

These words are Aristotle's not Zeno's, and indeed the argument is not even attributed to Zeno by Aristotle. However we have Simplicius' opinion ((a) *On Aristotle's Physics*, 139.24) that it originates with Zeno, which is why it is included here. Aristotle begins by hypothesizing that some body is completely divisible, 'through and through'; the second step of the argument makes clear that he means by this that it is divisible into parts that themselves have no size -- parts with any magnitude remain incompletely divided. (Once again what matters is that the body is genuinely composed of such parts, not that anyone has the time and tools to make the division.) So suppose the body is divided into its dimensionless parts. These parts could either be nothing at all -- as Zeno argued above -- or 'point-parts'. If the parts are nothing then so is the body: it's just an illusion. And, the argument concludes, even if they are points, since these are unextended the body itself will be unextended: surely any sum -- even an infinite one -- of zeroes is zero.

One could of course point out that it is only assumed that an infinity of zeroes is itself zero, and deny that assumption. However it has a strong intuitive pull, and once again one should show how any dimensionless points actually do make an extended whole. Fortunately Grünbaum (1967) showed how this is possible according to the modern mathematical treatment of a line. Consider a line segment of unit length. At its most basic level the segment is just a set of points -- if you take any spatial part of it, all you have is a point or set of points. Now Cantor gave a beautiful, astounding and extremely influential 'diagonal' proof that the number of points in the segment is uncountably infinite: there is no way to label *all* the points in the line with the infinity of numbers 1, 2, 3, … . As we noted above, it follows that we cannot apply the Cauchy definition of infinite sums to the points of the line, and so happily we cannot immediately conclude that because they all have zero length so does the whole line. But that still leaves open the question of how the line gets extension from its inextended points.

So suppose that you are just given the number of points in a line and that their lengths are all zero; how would you determine the length? Do we need a new definition, one that extends Cauchy's to uncountably infinite sums? It turns out that that would not help, because Cauchy further showed that any segment, of any length whatsoever (and indeed an entire infinite line) *have exactly the same number of points as our unit segment*. So knowing the number of points won't determine the length of the line, and so nothing like familiar addition -- in which the whole is determined by the parts -- is possible. Instead we must think of the distance properties of a line as logically posterior to its point composition: *first* we have a set of points (ordered in a certain way, so that there is some fact, for example, about which of any two is

before the other) *then* we define a function of two points which specifies how far apart they are (and which satisfies such conditions as that the distance between *A* and *B* plus the distance between *B* and *C* equals the distance between *A* and *C* -- assuming that *C* is not between *A* and *B*). By analogy, the maiden names of a married couple do not determine their surname: they could take either maiden name or hyphenate, or take a wholly new name if they choose. Thus we answer Zeno as follows: the argument assumed that the size of the body was a sum of the sizes of the point parts, but that is not the case; according to modern mathematics, a line is an uncountable infinity of points plus a distance function. (Note that Grünbaum used the fact that the point composition fails to determine a length to support his 'conventionalist' view that a line has no determinate length at all, independent of a standard of measurement.)

3. The Paradoxes of Motion

3.1 The Dichotomy

> The first asserts the non-existence of motion on the ground that that which is in locomotion must arrive at the half-way stage before it arrives at the goal. (Aristotle *Physics*, 239b11)

This paradox is known as the 'dichotomy' because it involves repeated division into two (like the second paradox of plurality). Like the other paradoxes of motion we have it from Aristotle, who sought to refute it.

Suppose a very fast runner -- such as mythical Atalanta -- needs to run for the bus. Clearly before she reaches the bus stop she must run half-way, as Aristotle says. There's no problem there; supposing a constant motion it will take her 1/2 the time to run half-way there and 1/2 the time to run the rest of the way. Now she must also run half-way to the half-way point -- i.e., a 1/4 of the total distance -- before she reaches the half-way point, but again she is left with a finite number of finite lengths to run, and plenty of time to do it. And before she reaches 1/4 of the way she must reach 1/2 of 1/4 = 1/8 of the way; and before that a 1/16; and so on. There is no problem at any finite point in this series, but what if the halving is carried out infinitely many times? The resulting series contains no first distance to run, for any possible first distance could be divided in half, and hence would not be first after all. However it does contain a final distance, namely 1/2 of the way; and a penultimate distance, 1/4 of the way; and a third to last distance, 1/8 of the way; and so on. Thus the series of distances that Atalanta is required to run is: …, then 1/16 of the way, then 1/8 of the way, then 1/4 of the way, and finally 1/2 of the way (of course we are not suggesting that she *stops* at the end of each segment and then starts running at the beginning of the next -- we are thinking of her continuous run being composed of such parts). And now there is a problem, for this description of her run has her travelling an *infinite* number of *finite* distances, which, Zeno would have us conclude, must take an infinite time, which is to say it is never completed. And since the argument does not depend on the distance or who or what the mover is, it follows that no finite distance can ever be traveled, which is to say that all motion is impossible. (Note that the paradox could easily be generated in the other direction so that Atalanta must first run half way, then half the remaining

way, then half of that and so on, so that she must run the following endless sequence of fractions of the total distance: 1/2, 1/4, 1/8 ….)

A couple of common responses are not adequate. One might -- as Simplicius ((a) *On Aristotle's Physics*, 1012.22) tells us Diogenes the Cynic did by silently standing and walking -- point out that it is a matter of the most common experience that things in fact do move, and that we know very well that Atalanta would have no trouble reaching her bus stop. But this would not impress Zeno, who as a paid up Parmenidean held that many things are not as they appear: it may appear that Diogenes is walking or that Atalanta is running, but appearances can be deceptive and surely we have a logical proof that they are in fact not moving at all. And if one doesn't accept that Zeno has given a proof that motion is illusory -- as we hopefully do not -- then one then owes an account of what is wrong with his argument: he has given reasons why motion is impossible, and so an adequate response must show why those reasons are not sufficient. And it won't do simply to point out that there are some ways of cutting up Atalanta's run -- into just two halves, say -- in which there is no problem. For if you accept all of the steps in Zeno's argument then you must accept his conclusion (assuming that he has reasoned in a logically deductive way): it's not enough to show an unproblematic division, you must also show why the given division is unproblematic.

Another response -- given by Aristotle himself -- is to point out that as we divide the distances run we should also divide the total time taken: there is 1/2 the time for the final 1/2, a 1/4 of the time for the previous 1/4, an 1/8 of the time for the 1/8 of the run and so on. Thus each fractional distance has just the right fraction of the finite total time for Atalanta to complete it, and thus the distance can be completed in a finite time. Aristotle felt that this reply should satisfy Zeno, however he also realized (*Physics*, 263a15) that this could not be the end of the matter (and surely Zeno would have made the same point if presented with Aristotle's response). For now we are saying that the *time* Atalanta takes to reach the bus stop is composed of an infinite number of finite pieces -- …, 1/8, 1/4, and 1/2 (of the total time) -- and isn't that an infinite time?

Of course, one could again claim that some infinite sums in fact have finite totals, and in particular that the sum of these pieces is 1 × the total time, which is of course finite (and again a complete solution would demand a rigorous account of infinite summation, like Cauchy's). However, Aristotle did not make such a move. What he said is worth noting because it had a considerable influence on later thinking about Zeno. In his response Aristotle drew a sharp distinction between what he termed a 'continuous' line and a line divided into parts. Consider a simple division of a line into two: on the one hand there is the undivided line, and on the other the line with a mid-point selected as the boundary of the two halves. Aristotle claims that these are two distinct things: and that the later is only 'potentially' derivable from the former. Next, Aristotle takes the common-sense view that time is like a geometric line, and considers the time it takes to complete the run. We can again distinguish the two cases: on the one hand there is the continuous run from start to finish, and on the other there is the run divided into Zeno's infinity of half-runs. The former is 'potentially infinite' in the sense that it could be divided into latter 'actual infinity'. Here's the crucial step: Aristotle thinks that since these times are *geometrically* distinct they must be *physically* distinct. But how could that be? He claims that the runner must do something at the end of each half-run to make it distinct from the next: she must stop. (Why stop rather than cough or something?

Because if the time is discontinuous then so is the motion.) And so Aristotle's full answer to the paradox is that Zeno's question -- whether the infinite series of runs is possible or not -- is ambiguous. One the one hand, the answer is 'yes' if one means the potentially infinite series that form the continuous run. On the other the answer is 'no' if one means the actual infinity of pieces that form the discontinuous run.

It is hard -- from our modern perspective perhaps -- to see how this answer could be completely satisfactory. In the first place it assumes that a clear distinction can be drawn between potential and actual infinities, something that was never fully achieved. Second, suppose that Zeno's problem turns on the claim that infinite sums of finite quantities are invariably infinite. Then Aristotle's distinction will only help if he can explain why potentially infinite sums are in fact finite (and couldn't I potentially add 1 + 1 + 1 + …, which does not have a finite total); or if he can give a reason why potentially infinite sums just don't exist. Or perhaps Aristotle did not see infinite sums as the problem, but rather whether completing an infinity of finite actions is metaphysically and conceptually and physically possible, an idea discussed at length in recent years: see 'Supertasks' below. In this case we need an account of actions that makes precise the sense in which the continuous run is indeed a single action (using rest to individuate motions seems problematic, for humans are probably never completely still, and yet we perform distinct motions -- breathing, eating, skipping and so on.) Finally, the distinction between potential and actual infinities has played no role in mathematics since Cantor tamed the transfinite numbers -- certainly the potential infinite has played no role in the modern mathematical solutions discussed here.

One last point: Zeno's argument seeks most obviously to establish the impossibility of motion, but he also intended it (and the following arguments) as further refutations of plurality -- certainly, Plato interprets Zeno's intentions in this way. How might the argument seek to establish this conclusion? Presumably Zeno has in mind the view that spatial (and perhaps temporal) distances have a plurality of parts; parts which are infinitely divisible into two. Given that assumption, supposedly finite distances (or times) can be decomposed into an infinity of finite parts with no first (or alternatively, last) one. And how can such distances be finite after all? And if the pluralist also believes in motion, how can such a distance be traversed? It seems it could not be.

3.2 Achilles and the Tortoise

> The [second] argument was called "Achilles," accordingly, from the fact that Achilles was taken [as a character] in it, and the argument says that it is impossible for him to overtake the tortoise when pursuing it. For in fact it is necessary that what is to overtake [something], before overtaking [it], first reach the limit from which what is fleeing set forth. In [the time in] which what is pursuing arrives at this, what is fleeing will advance a certain interval, even if it is less than that which what is pursuing advanced … . And in the time again in which what is pursuing will traverse this [interval] which what is fleeing advanced, in this time again what is fleeing will traverse some amount … . And thus in every time in which what is pursuing will traverse the [interval] which what is fleeing, being slower, has already advanced, what is fleeing will also advance some amount.

(Simplicius(b) *On Aristotle's Physics*, 1014.10)

This paradox turns on much the same considerations as the last. Imagine Achilles chasing a tortoise, and suppose that Achilles is running at 1 *m/s*, that the tortoise is crawling at 0.1 *m/s* and that the tortoise starts out 0.9 *m* ahead of Achilles. On the face of it Achilles should catch the tortoise after 1*s*, at a distance of 1*m* from where he starts (and so 0.1*m* from where the Tortoise starts). We could break Achilles' motion up as we did Atalanta's, into halves, or we could do it as follows: before Achilles can catch the tortoise he must reach the point where the tortoise started. But in the time he takes to do this the tortoise crawls a little further forward. So next Achilles must reach this new point. But in the time it takes Achilles to achieve this the tortoise crawls forward a tiny bit further. And so on to infinity: every time that Achilles reaches the place where the tortoise was the tortoise has had enough time to get a little bit further, and so Achilles has another run to make, and so Achilles has in infinite number of finite catch-ups to do before he can catch the tortoise, and so, Zeno concludes, he never catches the tortoise.

One aspect of the paradox is thus that Achilles must traverse the following infinite series of distances before he catches the tortoise: first 0.9*m*, then an additional 0.09*m*, then 0.009*m*, … . These are the series of distances ahead that the tortoise reaches at the start of each of Achilles' catch-ups. Looked at this way the puzzle is identical to the Dichotomy, for it is just to say that 'that which is in locomotion must arrive [nine tenths of the way] before it arrives at the goal'. And so everything we said above applies here too.

But what the paradox in this form brings out most vividly is the problem of completing a series of actions that has no final member -- in this case the infinite series of catch-ups before Achilles reaches the tortoise. But just what is the problem? Perhaps the following: Achilles' run to the point at which he should reach the tortoise can, it seems, be completely decomposed into the series of catch-ups, none of which take him to the tortoise. Therefore, nowhere in his run does he reach the tortoise after all. But if this is what Zeno had in mind it won't do. Of course Achilles doesn't reach the tortoise at any point of the sequence, for every run in the sequence occurs *before* we expect Achilles to reach it! Thinking in terms of the points that Achilles must reach in his run, 1m does not occur in the sequence 0.9*m*, 0.99*m*, 0.999*m*, … , so of course he never catches the tortoise during that sequence of runs! The series of catch-ups does not after all completely decompose the run: the final point -- at which Achilles does catch the tortoise -- must be added to it. So is there any puzzle? Arguably yes.

Achilles run passes through the sequence of points 0.9*m*, 0.99*m*, 0.999*m*, … , 1*m*. But does such a strange sequence -- comprised of an infinity of members followed by one more -- make sense mathematically? If not then our mathematical description of the run cannot be correct, but then what is? Fortunately the theory of transfinites pioneered by Cantor assures us that such a series is perfectly respectable. It was realized that the order properties of infinite series are much more elaborate than those of finite series. Any way of arranging the numbers 1, 2 and 3 gives a series in the same pattern, for instance, but there are many distinct ways to order the natural numbers: 1, 2, 3, … for instance. Or … , 3, 2, 1. Or … , 4, 2, 1, 3, 5, … . Or 2, 3, 4, … , 1, which is just the same kind of series as the positions Achilles must run through. Thus the theory of the transfinites treats not just 'cardinal' numbers -- which depend only on how many things there are -- but also 'ordinal' numbers which depend further on how the things are arranged. Since the ordinals are standardly taken to be mathematically legitimate numbers, and

since the series of points Achilles must pass has an ordinal number, we shall take it that the series is mathematically legitimate. (Again, see ‘Supertasks’ below for another kind of problem that might arise for Achilles’.)

3.3 The Arrow

> The third is … that the flying arrow is at rest, which result follows from the assumption that time is composed of moments … . he says that if everything when it occupies an equal space is at rest, and if that which is in locomotion is always in a now, the flying arrow is therefore motionless. (Aristotle *Physics*, 239b.30)
>
> Zeno abolishes motion, saying "What is in motion moves neither in the place it is nor in one in which it is not". (Diogenes Laertius *Lives of Famous Philosophers*, ix.72)

This argument against motion explicitly turns on a particular kind of assumption of plurality: that time is composed of moments (or ‘nows’) *and nothing else*. Consider an arrow, apparently in motion, at any instant. First, Zeno assumes that it travels no distance during that moment -- ‘it occupies an equal space’ for the whole instant. But the entire period of its motion contains only instants, all of which contain an arrow at rest, and so, Zeno concludes, the arrow cannot be moving.

An immediate concern is why Zeno is justified in assuming that the arrow is at rest during any instant. It follows immediately if one assumes that an instant lasts 0s: whatever speed the arrow has, it will get nowhere if it has no time at all. But what if one held that the smallest parts of time are finite -- if tiny -- so that a moving arrow might actually move some distance during an instant? One way of supporting the assumption -- which requires reading quite a lot into the text we have -- is to assume that instants are indivisible. Then suppose that an arrow actually moved during an instant. It would be at different locations at the start and end of the instant, which implies that the instant has a ‘start’ and an ‘end’, which in turn implies that it has at least two parts, and so is divisible, and so is not an indivisible moment at all. (Note that this argument only establishes that nothing can move during an instant, not that instants cannot be finite.)

So then, nothing moves during any instant, but time is entirely composed of instants, so nothing ever moves. A first response is to point out that determining the velocity of the arrow means dividing the distance traveled in some time by the length of that time. But -- assuming from now on that instants have zero duration -- this formula makes no sense in the case of an instant: the arrow travels 0*m* in the 0*s* the instant lasts, but 0/0 *m/s* is not any number at all. Thus it is fallacious to conclude from the fact that the arrow doesn’t travel any distance in an instant that it is at rest; whether it is in motion at an instant or not depends on whether it travels any distance in a *finite* interval that includes the instant in question.

The answer is correct, but it carries the counter-intuitive implication that motion is not something that happens at any instant, but rather only over finite periods of time. Think about it this way: time, as we said, is composed only of instants. No distance is traveled during any instant. So when does the arrow

actually move? How does it get from one place to another at a later moment? There's only one answer: the arrow gets from point *X* at time 1 to point *Y* at time 2 simply in virtue of being at successive intermediate points at successive intermediate times -- the arrow never changes its position during an instant but only over intervals composed of instants, by the occupation of different positions at different times. In Bergson's memorable words -- which he thought expressed an absurdity -- 'movement is composed of immobilities' (1911, 308): getting from *X* to *Y* is a matter of occupying exactly one place in between at each instant (in the right order of course).

3.4 The Stadium

> The fourth argument is that concerning equal bodies [*AA*] which move alongside equal bodies in the stadium from opposite directions -- the ones from the end of the stadium [*CC*], the others from the middle [*BB*] -- at equal speeds, in which he thinks it follows that half the time is equal to its double…. And it follows that the *C* has passed all the *A*s and the *B* half; so that the time is half … . And at the same time it follows that the first *B* has passed all the *C*s. (Aristotle *Physics*, 239b33)

The final paradox of motion runs as follows: picture three sets of three touching cubes -- all nine exactly the same, with side L m -- in relative motion. One set -- the *A*s --are at rest, and the others -- the *B*s and *C*s -- move from the left and right respectively, at a constant equal speed, *S m/s*. And suppose that at some moment the rightmost *B* is perfectly aligned with the middle *A*, and the leftmost *C* with the rightmost *A*: thus the edges of the rightmost *B* and leftmost *C* are exactly lined up. That is they are arranged as shown.

```
   A A A
 B B B
       C C C
```

Now consider the later time at which the rightmost *A* and *B* are aligned; since the speeds of the *B*s and *C*s are equal, at this moment the middle *A* will be aligned with the leftmost *C*. That is consider the moment when the blocks are configured thus.

```
 A A A
 B B B
   C C C
```

This motion requires the rightmost *B* to move one block -- a distance *L m* -- to the right, at a speed of *S m/s*, so it takes *L/S s*. And the same motion also requires the leftmost *C* to move from just to the right of the rightmost *B* into alignment with the middle *B*, a distance a distance of 2*L m*. So far so good, but now Zeno concludes that since the *C*s are moving at *S m/s*, the motion must also take 2*L/S s*. And hence 'half

the time [L/S] is equal to its double [$2L/S$]', since one and the same motion seems to take both times.

The unanimous verdict on Zeno is that he was hopelessly confused about relative velocity in this paradox. If the *B*s are moving with speed S m/s to the right with respect to the *A*s and if the *C*s are moving with speed *S m/s* to the left with respect to the *A*s then the *C*s are moving with speed $S+S = 2S$ *m/s* to the left with respect to the *B*s. And so, as expected it takes the *C*s $2L/2S = L/S$ *s* to complete the motion after all.

This resolution notwithstanding, recent philosophers have attempted to put a new spin on Zeno's argument (it's arguable whether Zeno himself had anything like what follows in mind). This argument opposed the view that space and time are 'quantized', composed of smallest finite parts. Suppose they are and that *L m* is the 'quantum' of length and that the two moments considered are separated by a single quantum of time. Now something strange has happened, for the rightmost *B* and the leftmost *C* have clearly passed each other during the motion, and yet there is no moment at which they are level: since the two moments are separated by the smallest possible time, there can be no moment between them -- it would be a time smaller than the smallest time from the two moments we considered. Conversely, if one insisted that if they pass then there must be a moment when they are level, then it shows that cannot be a shortest finite interval -- whatever it is, just run this argument against it. However, why should one insist on this assumption? The problem is that one naturally imagines quantized space as being like a chess board, on which the chess pieces are frozen during each quantum of time. Then one wonders when the red queen, say, gets from one square to the next, or how she gets past the white queen without being level with her. But the analogy is misleading. It is better to think of quantized space as a giant matrix of lights that holds some pattern of illuminated lights for each quantum of time. In this analogy a lit bulb represents the presence of an object: for instance a series of bulbs in a line lighting up in sequence represent a body moving in a straight line. In this case there is no temptation to ask when the light 'gets' from one bulb to the next -- or in analogy how the body moves from one location to the next.

4. Two More Paradoxes

4.1 The Paradox of Place

> Zeno's difficulty demands an explanation; for if everything that exists has a place, place too will have a place, and so on *ad infinitum*. (Aristotle *Physics*, 209a23)

When he sets up his theory of place -- the crucial spatial notion in his theory of motion -- Aristotle lists various theories and problems that his predecessors, including Zeno, have formulated on the subject. One can again see here a problem for pluralism, for the second step of the argument concludes that there are many places. It is perhaps a little hard to feel the full force of the conclusion, for why should there not be an infinite series of places of places of places of …? Presumably the worry would be greater for someone who (like Aristotle) believed that there could not be an actual infinity of things, for the argument seems to show that there are. But certainly today we need have no such qualms; there seems nothing

problematic with an actual infinity of places; indeed, it seems very natural to think that every point of space is a distinct place, even if there are an infinity of points.

The only other way one might find the regress troubling is if one had reason to suppose that objects must have ‘absolute’ places, in the sense that there is always a unique answer to the question ‘where is it’? For example, where am I as I write? If the paradox is right then I’m in my place, and I’m also in my place’s place, and my place’s place’s place, and my … . Since I’m in all these places any might seem an appropriate answer to the question. But why think that there must be a unique answer to the question? Why shouldn’t I have many locations? At my desk, in my apartment, in Chicago, Illinois, USA, North America, the Earth, Solar System … . (In fact there is a reason that Aristotle might have had this concern about Zeno’s argument, for in his theory of motion, the natural motion of a body is determined by the relation of its place to the center of the universe: an account that only makes sense if bodies can be attributed a unique place. Interestingly, Newton, in the Scholium to the principal Definitions in Book I of his *Principia*, gives an argument along similar lines: he assumes that every body has a unique, absolute velocity, and argues that only a fixed matter-independent, ‘absolute’ space will provide such uniqueness. That said, there is no evidence either that Zeno had this kind of argument in mind, or that Newton was influenced by Aristotle in this regard.)

4.2 The Grain of Millet

> … Zeno’s reasoning is false when he argues that there is no part of the millet that does not make a sound; for there is no reason why any part should not in any length of time fail to move the air that the whole bushel moves in falling. (Aristotle *Physics*, 250a19)

This argument is a Parmenidean argument against the reliability of the senses. It goes like this: if you drop a sack of millet on the floor then you hear a loud thud; but this noise is the result of the noise made by every grain of millet in the sack; and the result of the noise made by every part of every grain; therefore every part of every grain makes a noise as it hits the ground. But now consider dropping a tiny part of a grain; we know that we won’t hear it. Therefore our sense of hearing is deceptive -- there are noises it cannot hear -- and so we should not trust it. Aristotle’s response seems to be that the part would not move as much air as the sack, but the paradox is not that the part should make as much noise as the sack, but that it should make some noise. A better reply is surely that not every disturbance in the air is audible by us: that a measuring instrument is unreliable over some range is no argument that it is unreliable over every range.

5. Zeno’s Influence on Philosophy

In this final section we should consider briefly the impact that Zeno has had on various philosophers; a search of the literature will reveal that these debates continue.

- The Pythagoreans: For the first half of the Twentieth century the majority reading -- following

Tannery (1885) -- of Zeno held that his arguments were directed against a technical doctrine of the Pythagoreans. According to this reading they held that all things were composed of elements that had the properties of a unit number, a geometric point and a physical atom: this kind of position would fit with their doctrine that reality is fundamentally mathematical. However, in the middle of the century a series of commentators (Vlastos, 1967, summarizes the argument and contains references) forcefully argued that Zeno’s target was instead a common sense understanding of plurality and motion -- one grounded in familiar geometrical notions -- and indeed that the doctrine was not a major part of Pythagorean thought. We have implicitly assumed that these arguments are correct in our readings of the paradoxes. That said, Tannery’s interpretation still has its defenders (see e.g., Matson 2001).

- The Atomists: Aristotle (*On Generation and Corruption* 316b34) claims that our third argument -- the one concerning complete divisibility -- was what convinced the atomists that there must be smallest, indivisible parts of matter. See Abraham (1972) for a further discussion of Zeno’s connection to the atomists.

- Temporal Becoming: In the early part of the Twentieth century several influential philosophers attempted to put Zeno’s arguments to work in the service of a metaphysics of ‘temporal becoming’, the (supposed) process by which the present comes into being. Such thinkers as Bergson (1911), James (1911, Ch 10 -11) and Whitehead (1929) argued that Zeno’s paradoxes show that space and time are not structured as a mathematical continuum: they argued that the way to preserve the reality of motion was to deny that space and time are composed of points and instants. However, we have clearly seen that the tools of standard modern mathematics are up to the job of resolving the paradoxes, so no such conclusion seems warranted: if the present indeed ‘becomes’, there is no reason to think that the process is not captured by the continuum.

- Applying the Mathematical Continuum to Physical Space and Time: Following a lead given by Russell (1929, 182-198), a number of philosophers -- most notably Grünbaum (1967) -- took up the task of showing how modern mathematics could solve all of Zeno’s paradoxes; their work has thoroughly influenced our discussion of the arguments. What they realized was that a purely mathematical solution was not sufficient: the paradoxes not only question abstract mathematics, but also the nature of physical reality. So what they sought was an argument not only that Zeno posed no threat to the mathematics of infinity but also that that mathematics correctly describes objects, time and space. The idea that a mathematical law -- say Newton’s law of universal gravity -- may or may not correctly describe things is familiar, but some aspects of the mathematics of infinity -- the nature of the continuum, definition of infinite sums and so on -- seem so basic that it may be hard to see at first that they too apply contingently. But surely they do: nothing guarantees *a priori* that space has the structure of the continuum, or even that parts of space add up according to Cauchy’s definition. (Salmon offers a nice example to help make the point: since alcohol dissolves in water, if you mix the two you end up with less than the sum of their volumes, showing that even ordinary addition is not applicable to every kind of system.) Our belief that the mathematical theory of infinity describes space and time is justified to the extent that the laws of physics assume that it does, and to the extent that those laws are themselves

confirmed by experience. While it is true that almost all physical theories assume that space and time do indeed have the structure of the continuum, it is also the case that quantum theories of gravity likely imply that they do not. While no one really knows were this research will ultimately lead, it is quite possible that space and time will turn out, at the most fundamental level, to be quite unlike the mathematical continuum that we have assumed here.

One should also note that Grünbaum took the job of showing that modern mathematics describes space and time to involve something rather different from arguing that it is confirmed by experience. The dominant view at the time (though not at present) was that scientific terms had meaning insofar as they referred directly to objects of experience -- such as ‘1 m ruler’ -- or, if they referred to ‘theoretical’ rather than ‘observable’ entities -- such as ‘a point of space’ or ‘1/2 of 1/2 of … 1/2 a racetrack’ -- then they obtained meaning by their logical relations -- via definitions and theoretical laws -- to such observation terms. Thus Grünbaum undertook an impressive program to give meaning to all terms involved in the modern theory of infinity, interpreted as an account of space and time.

- Supertasks: A further strand of thought concerns what Black (1950-51) dubbed ‘infinity machines’. Black and his followers wished to show that although Zeno’s paradoxes offered no problem to mathematics, they showed that after all mathematics was not applicable to space, time and motion. Most starkly, our resolution to the Dichotomy and Achilles assumed that the complete run could be broken down into an infinite series of half runs, which could be summed. But is it really possible to complete any infinite series of actions: to complete was is known as a ‘supertask’? If not, and assuming that Atalanta and Achilles can complete their tasks, their complete runs cannot be correctly described as an infinite series of half-runs, although modern mathematics would so describe them. What infinity machines are supposed to establish is that an infinite series of tasks cannot be completed -- so any completable task cannot be broken down into an infinity of smaller tasks, whatever mathematics suggests.

- Non-standard analysis: Finally, we have seen how to tackle the paradoxes using the resources of mathematics as developed in the Nineteenth century. For a long time it was considered one the great virtues of this system that it finally showed how to do without infinitesimal quantities, smaller than any finite number but larger than zero. (Newton’s calculus for instance effectively made use of such numbers, treating them sometimes as zero and sometimes as finite; the problem with such an approach is that how to treat the numbers is a matter of intuition not rigor.) However, in the Twentieth century Robinson showed how to introduce infinitesimal numbers into mathematics: this is the system of ‘non-standard analysis’ (the familiar system of real numbers, given a rigorous foundation by Dedekind, is by contrast just ‘analysis’). And it has been shown by McLaughlin (1992, 1994) that Zeno’s paradoxes can also be resolved in non-standard analysis; they are no more argument against non-standard analysis than the standard mathematics we have assumed here. It should be emphasized however that -- contrary to McLaughlin’s suggestions -- there is no need for non-standard analysis to solve the paradoxes: either system is equally successful. (The construction of non-standard analysis does however raise a further question about

the applicability of analysis to physical space and time: it seems plausible that all physical theories can be formulated in either terms, and so as far as our experience extends both seem equally confirmed. But they cannot both be true of space and time: either space has infinitesimal parts or it doesn't.)

Further Readings

After the relevant entries in this encyclopedia, the place to begin any further investigation is Salmon (2001), which contains some of the most important articles on Zeno up to 1970, and an impressively comprehensive bibliography of works in English in Twentieth Century.

One might also take a look at Huggett (1999, Ch. 3) for further source passages and discussion. For a discussion of the influence of the paradoxes through the Nineteenth century there is Cajori. For introductions to the mathematical ideas behind the modern resolutions, the Appendix to Salmon (2001) is a good start; Russell (1919) and Courant *et al*. (1996, Chs. 2 and 9) are also both wonderful sources. Finally, three collections of original sources for Zeno's paradoxes: Lee (1936) contains everything known, Kirk *et al* (1983, Ch. 9) contains a great deal of material (in English and Greek) with useful commentaries, and Cohen *et al*. (1995) also has the main passages.

Supertasks

Supertasks have posed problems for philosophy since the time of Zeno of Elea. The term ‘supertask’ is new but it designates an idea already present in the formulation of the old motion paradoxes of Zeno, namely the idea of an infinite number of actions performed in a finite amount of time. The main problem lies in deciding what follows from the performance of a supertask. Some philosophers have claimed that what follows is a contradiction and that supertasks are, therefore, logically impossible. Others have denied this conclusion, and hold that the study of supertasks can help us improve our understanding of the physical world, or even our theories about it.

Section 1: What is a Supertask

1.1: Definitions

A supertask may be defined as an infinite sequence of actions or operations carried out in a finite interval of time. The terms ‘action’ and ‘operation’ must not be understood in their usual sense, which involves a human agent. Human agency may be involved but it is not necessary. To show this, let us see how actions can be characterised precisely without any references to man. We will assume that at each instant of time the state of the world relevant to a specific action can be described by a set S of sentences. Now an action or operation applied to a state of the world results in a change in that state, that is, in the set S corresponding to it. Consequently, an arbitrary action a will be defined (Allis and Koetsier [1995]) as a change in the state of the world by which the latter changes from state S before the change to state a(S) after it. This means that an action has a beginning and an end, but does not entail that there is a finite lapse of time between them. For instance, take the case of a lamp that is on at t = 0 and remains so until t = 1, an instant at which it suddenly goes off. Before t =1 the state of the lamp (which is the only relevant portion of the world here) can be described by the sentence ‘lamp on’, and after t =1 by the sentence ‘lamp off’, without there being a finite lapse of time between the beginning and the end of the action. Some authors have objected to this consequence of the definition of action, and they might be right if we were dealing with the general philosophical problem of change. But we need not be concerned with those objections at this stage, since in the greatest majority of the relevant supertasks instantaneous actions (i.e. actions without any duration) can be replaced by actions lasting a finite amount of time without affecting the analysis at any fundamental point.

There is a particular type of supertask called *hypertasks*. A hypertask is a non-numerable infinite sequence of actions or operations carried out in a finite interval of time. Therefore, a supertask which is not a hypertask will be a numerable infinite sequence of actions or operations carried out in a finite interval of time. Finally, a task can be defined as a finite sequence of actions or operations carried out in a finite interval of time.

1.2: The Philosophical Problem of Supertasks

To gain a better insight into the fundamental nature of the philosophical problem posed by supertasks, consider the distinction between tasks in general (finite sequences of actions of the type (a_1, a_2, a_3, . . . , a_n)) and one particular type of supertasks, namely those consisting of an infinite sequence of actions of the type (a_1, a_2, a_3, . . . , a_n, . . .) and thus having the same type of order as the natural order of positive integers: 1, 2, 3, . . . , n, . . . (it is customary to denote this type of order with letter ‘*w*’ and so the related supertasks can be called supertasks of type *w*).

In the case of a task T = (a_1, a_2, a_3, . . . , a_n) it is natural to say that T is applicable in state S if:

> a_1 is applicable to S,
> a_2 is applicable to a_1(S),
> a_3 is applicable to a_2(a_1(S)),
> . . . , and,
> a_n is applicable to $a_{n-1}(a_{n-2}(. . . (a_2(a_1(S))). . .))$.

The successive states of the world relevant to task T can be defined by means of the finite sequence of sets of sentences:

$$S, \quad a_1(S), \quad a_2(a_1(S)), \quad a_3(a_2(a_1(S))), \quad \ldots \quad , a_n(a_{n-1}(a_{n-2} (\ldots (a_2(a_1(S)))\ldots))),$$

whose last term will therefore describe the relevant state of the world after the performance of T. Or, equivalently, the state resulting from applying T to S will be T(S) =

$$a_n(a_{n-1}(a_{n-2} (\ldots (a_2(a_1(S)))\ldots))).$$

Now take the case of a supertask T = (a_1, a_2, a_3, . . . , a_n, . . .). Let us give the name T_n to the task which consists in performing the first n actions of T. That is, T_n = (a_1, a_2, a_3, . . . , a_n). Now it is natural to say that T is applicable in state S if T_n is applicable in S for each natural number n, and, obviously,

$$T_n(S) \quad = \quad a_n(a_{n-1}(a_{n-2} (\ldots (a_2(a_1(S)))\ldots))).$$

The successive states of the world relevant to supertask T can be described by means of the infinite sequence of sets of sentences:

$$S, \quad T_1(S), \quad T_2(S), \quad \ldots \quad , T_n(S), \quad \ldots$$

A difficulty arises, however, when we want to specify the set of sentences which describe the relevant state of the world after the performance of supertask T, because the infinite sequence above lacks a final term. Put equivalently, it is difficult to specify the relevant state of the world resulting from the application of supertask T to S because there seems to be no final state resulting from such an application. This inherent difficulty is increased by the fact that, by definition, supertask T is performed in a finite time, and so there must exist one first instant of time t* at which it can be said that the performance happened. Now notice that the world must naturally be in a certain specific state at t*, which is the state resulting from the application of T, but that, nevertheless, we have serious trouble to specify this state, as we have just seen.

1.3: Supertask: A Fuzzy Concept

Since we have defined supertasks in terms of actions and actions in terms of changes in the state of the world, there is a basic indeterminacy regarding what type of processes taking place in time should be considered supertasks, which is linked to the basic indeterminacy that there is regarding which type of sets of sentences are to be allowed in descriptions of the state of the world and which are not. For this reason, there are some processes that would be regarded as supertasks by virtually every philosopher and some about which opinions differ. For an instance of the first sort of process, take the one known as ‘Thomson's lamp’. Thomson's lamp is basically a device consisting of a lamp and a switch set on an electrical circuit. The switch can be in one of just two positions and the lamp has got to be lit -when the switch is in position ‘on’- or else dim -when the switch is in position ‘off’. Assume that initially (at t = 12 A.M., say) the lamp is dim and that it is thenceforth subject to the following infinite sequence of actions: when half of the time remaining until t* = 1 P.M. has gone by, we carry out the action a_1 of turning the switch into position ‘on’ and, as a result, the lamp is lit (a_1 is thus performed at t = 1/2 P.M.); when half the time between the performance of a_1 and t* = 1 P.M. has gone by, we carry out action a_2 of turning to the switch into position ‘off’ and, as a result, the lamp is dim (a_2 is thus performed at t = 1/2 + 1/4 P.M.); when half the time between the performance of a_2 and t* = 1 P.M. has gone by, we carry out the action of turning the switch into position ‘on’ and, as a result, the lamp is lit (a_3 is thus performed at t = 1/2 + 1/4 + 1/8), and so on. When we get to instant t* = 1 P.M. we will have carried out an infinite sequence of actions, that is, a supertask T = (a_1, a_2, a_3, . . . , a_n, . . .). If, for the sake of simplicity, we are only concerned about the evolution of the lamp (not the switch) the state of the world relevant to the description of our supertask admits of only two descriptions, one through the unitary set of sentences {lamp lit} and the other through the set {lamp dim}.

As an instance of the second sort of processes we referred to above, those about which no consensus has been reached as to whether they are supertasks, we can take the process which is described in one of the forms of Zeno's dichotomy paradox. Suppose that initially (at t = 12 A.M., say) Achilles is at point A (x = 0) and moving in a straight line, with a constant velocity v = 1 km/h, towards point B (x = 1), which is 1 km. away from A. Assume, in addition, that Achilles does not modify his velocity at any point. In that case, we can view Achilles's run as the performance of a supertask, in the following way: when half the time until t* = 1 P.M. has gone by, Achilles will have carried out the action a_1 of going from point x = 0 to point x = 1/2 (a_1 is thus performed in the interval of time between t =12 A.M. and t = 1/2 P.M.), when half the time from the end of the performance of a_1 until t* = 1 P.M. will have elapsed, Achilles will have carried out the action a_2 of going from point x = 1/2 to point x = 1/2 + 1/4 (a_2 is thus performed in the interval of time between t = 1/2 P.M. and t = 1/2 + 1/4 P.M.), when half the time from the end of the performance of a_2 until t* = 1 P.M. will have elapsed, Achilles will have carried out the action a_3 of going from point x = 1/2 + 1/4 to point x = 1/2 + 1/4 + 1/8 (a_3 is thus performed in the interval of time between t = 1/2 + 1/4 P.M. and t = 1/2 + 1/4 + 1/8 P.M.), and so on. When we get to instant t* = 1 P.M., Achilles will have carried out an infinite sequence of actions, that is, a supertask T = (a_1, a_2, a_3, . . . , a_n, . . .), provided we allow the state of the world relevant for the description of T to be specified, at any arbitrary instant, by a single sentence: the one which specifies Achilles's position at that instant. Several

philosophers have objected to this conclusion, arguing that, in contrast to Thomson's lamp, Achilles's run does not involve an infinity of actions (acts) but of pseudo-acts. In their view, the analysis presented above for Achilles's run is nothing but the breakdown of one process into a numerable infinity of subprocesses, which does not make it into a supertask. In Allis and Koetsier's words, such philosophers believe that a set of position sentences is not always to be admitted as a description of the state of the world relevant to a certain action. In their opinion, a relevant description of a state of the world should normally include a different type of sentences (as is the case with Thomson's lamp) or, in any case, more than simply position sentences.

Section 2: On The Conceptual Possibility Of Supertasks

In section 1.2 I have pointed out and illustrated the fundamental philosophical problem posed by supertasks. Obviously, one will only consider it a problem if one deems the concepts employed in its formulation acceptable. In fact, some philosophers reject them, because they regard the very notion of supertask as problematic, as leading to contradictions or at least to insurmountable conceptual difficulties. Among these philosophers the first well-known one is Zeno of Elea.

2.1: Zeno's Dichotomy Paradox

Consider the dichotomy paradox in the formulation of it given in section 1.3. According to Zeno, Achilles would never get to point B ($x = 1$) because he would first have to reach the mid point of his run ($x = 1/2$), after that he would have to get to the mid point of the span which he has left ($x = 1/2 + 1/4$), and then to the mid point of the span which is left ($x = 1/2 + 1/4 + 1/8$), and so on. Whatever the mid point Achilles may reach in his journey, there will always exist another one (the mid point of the stretch that is left for him to cover) that he has not reached yet. In other words, Achilles will never be able to reach point B and finish his run. According to Owen (Owen [1957-58]), in this as well as in his other paradoxes, Zeno was concerned to show that the Universe is a simple, global entity which is not comprised of different parts. He tried to demonstrate that if we take to making divisions and subdivisions we will obtain absurd results (as in the dichotomy case) and that we must not yield to the temptation of breaking up the world. Now the notion of supertask entails precisely that, division into parts, as it involves breaking up a time interval into successive intervals. Therefore, supertasks are not feasible in the Zenonian world and, since they lead to absurd results, the notion of supertask itself is conceptually objectionable.

In stark contrast to Zeno, the dichotomy paradox is standardly solved by saying that the successive distances covered by Achilles as he progressively reaches the mid points of the spans he has left to go through --- 1/2, 1/4, 1/8, 1/16, . . . --- form an infinite series $1/2 + 1/4 + 1/8 + 1/16 + \ldots$ whose sum is 1. Consequently, Achilles will indeed reach point B ($x = 1$) at $t^* = 1$ P.M. (which is to be expected if he travels with velocity $v = 1$ km/h, as has been assumed). Then there is no problem whatsoever in splitting up his run into smaller sub-runs and, so, no inherent problem about the notion of supertask. An objection can be made, however, to this standard solution to the paradox: it tells us where Achilles is at each instant

but it does not explain where Zeno's argument breaks down. Importantly, there is another objection to the standard solution, which hinges on the fact that, when it is claimed that the infinite series 1/2 + 1/4 + 1/8 + 1/16 + . . . adds up to 1, this is substantiated by the assertion that the sequence of partial sums 1/2, 1/2 + 1/4, 1/2 + 1/4 + 1/8, . . . has limit 1, that is, that the difference between the successive terms of the sequence and number 1 becomes progressively smaller than any positive integer, no matter how small. But it might be countered that this is just a patch up: the infinite series 1/2 + 1/4 + 1/8 + . . . seems to involve infinite sums and thus the performance of a supertask, and the proponent of the standard solution is in fact presupposing that supertasks are feasible just in order to justifiy that they are. To this the latter might reply that the assertion that the sum of the series is 1 presupposes no infinite sum, since, by definition, the sum of a series is the limit to which its partial (and so finite) sums approach. His opponent can now express his disagreement with the response that the one who supports the standard solution is deducing a matter of fact (that Achilles is at $x = 1$ at t* = 1 P.M.) from a definition pertaining to the arithmetic of infinite series, and that it is blatantly unacceptable to deduce empirical propositions from mere definitions.

2.2: The Inverse Form Of The Dichotomy Argument

Before concluding our discussion of the arguments connected with Zeno's dichotomy paradox which have been put forward against the conceptual feasibility of supertasks, we should deal with the so-called inverse dichotomy of Zeno, which can also be formulated as a supertask, but whose status as a logical possibility seems to some philosophers to be even more doubtful than that of the direct version expounded in section 2.1. The process involved in the paradox of inverse dichotomy admits of a supertask kind of description, as follows. Suppose that at t = 12 A.M. Achilles is at point A ($x = 0$) and wishes to do the action of reaching point B ($x = 1$). In order to do this action he must first of all go from point A to the mid point b_1 ($x = 1/2$) of the span AB that he wishes to cover. In order to do this, he must in turn first do the action of going from point A to the mid point b_2 ($x = 1/4$) of the span Ab_1 that he wishes to cover, and so on . In order to reach B, Achilles will have to accomplish an infinite sequence of actions, that is, a supertask T* = (. . . , a_n, . . . , a_3, a_2, a_1), provided we allow the state of the world relevant to the description of T* to be specified, at a given arbitrary instant, by a single sentence, the one specifying Achilles's position at that instant. Notice in the first place that T* has the same type of order as the natural order of negative integers: . . . , -n, . . . , -3, -2, -1 (such order type is usually denoted with the expression '*w**' and the related supertasks can therefore be called supertasks of type *w**). The philosophical problem connected with supertasks of type *w*, already discussed in section 1.2 above, does not arise now because the set of sentences which describes the relevant state of the world after the performance of supertask T* is obviously a_1(S), with S the set of sentences describing the initial relevant state of the world. But as the successive states of the world after S in relation to T* can be described by means of the infinite sequence of sets of sentences . . . , a_n(S), . . . , a_3(S), a_2(S), a_1(S), some philosophers think it puzzling and unacceptable that the initial set of sentences in that sequence cannot be specified. This really means that we cannot specify which is the action in supertask T* that should be carried out first and that we consequently ignore how to begin. Isn't that proof enough that supertasks of type *w** are impossible? Chihara (1965), for example, says that Zeno's inverse dichotomy is even more problematic than the direct one, since Achilles is supposed to be capable of doing something akin to counting the

natural numbers in reverse order. In his opinion, it is just as impossible for Achilles to start his run -- if viewed as a supertask of type *w** -- as it is to start this reverse counting process.

2.3: On Thomson's Impossibility Arguments

Thomson (1954-55) was convinced that he could show supertasks to be logically impossible. To this end, he made up the lamp example analysed in section 1.3, since known as ‘Thomson's lamp’. Thomson argued that the analysis of the workings of his lamp leads to contradiction, and therefore the supertask involved is logically impossible. But then, to the extent that this supertask is representative of ‘genuine’ supertasks, all genuine supertasks are impossible. Thomson's argument is simple. Let us ask ourselves what the state of the lamp is at t* = 1 P.M. At that instant the lamp cannot be lit, the reason being the way we manipulate it: we never light the lamp without dimming it some time later. Nor can the lamp be dim, because even if it is dim initially, we light it and subsequently never dim it without lighting it back again some time later. Therefore,at t* = 1 P.M. the lamp can be neither dim nor lit. However, one of its functioning conditions is that it must be either dim or lit. Thus, a contradiction arises. Conclusion: Thomson's lamp or, better, the supertask consisting in its functioning is logically impossible. Now is Thomson's argument correct? Benacerraf (1962) detected a serious flaw in it. Let us in principle distinguish between the series of instants of time in which the actions a_i of the supertask are performed (which will be called the t-series) and the instant t* = 1 P.M., the first instant after the supertask has been accomplished. Thomson's argument hinges on the way we act on the lamp, but we only act on it at instants in the t-series, and so what can be deduced logically from this way of acting will apply only to instants in the t-series. As t* = 1 P.M. does not belong to the t-series, it follows that Thomson's supposed conclusion that the lamp cannot be lit at t* is fallacious, and so is his conclusion that it cannot be dim at t*. The conditions obtaining in the lamp problem only enable us to conclude that the lamp will be either dim or else lit but not both at t* = 1 P.M., and this follows from the fact that this exclusive disjunction was presupposed from the start to be true at each and every instant of time, independently of the way in which we could act on the lamp in the t-series of instants of time. What cannot be safely inferred is which one of these two states -dim or lit- the lamp will be in at t* = 1 P.M. or, alternatively, the state of the lamp at t* = 1 P.M. is not logically determined by what has happened before that instant. This consequence tallies with what was observed in section 2.1 about the fallacy committed by adherents to the standard solution against Zeno: they seek to deduce that at instant t* = 1 P.M. Achilles will be at point B from an analysis of the sub-runs performed by him before that instant, that is, they assume that Achilles's state at t* follows logically from his states at instants previous to t*, and in so assuming they make the same mistake as Thomson.

Thomson (1954-55) put forward one more argument against the logical possibility of his lamp. Let us assign to the lamp the value 0 when it is dim and the value 1 when it is lit. Then lighting the lamp means adding one unity (going from 0 to 1) and dimming it means subtracting one unity (going from 1 to 0). It thus seems that the final state of the lamp at t* = 1 P.M., after an infinite, and alternating, sequence of lightings (additions of one unity) and dimmings (subtractions of one unity), should be described by the infinite series 1-1+1-1+1. . . If we accept the conventional mathematical definition of the sum of a series, this series has no sum, because the partial sums 1, 1-1, 1-1+1, 1-1+1-1, . . . , etc. take on the values 1 and

0 alternatively, without ever approaching a definite limit that could be taken to be the proper sum of the series. But in that case it seems that the final state of the lamp can neither be dim (0) nor lit (1), which contradicts our assumption that the lamp is at all times either dim or lit. Benacerraf's (1962) reply was that even though the first, second, third, . . . , n-th partial sum of the series 1-1+1-1+1. . . does yield the state of the lamp after one, two, three, . . . , n actions a_i (of lighting or dimming), it does not follow from this that the final state of the lamp after the infinite sequence of actions a_i must of necessity be given by the sum of the series, that is, by the limit to which its partial sums progressively approach. The reason is that a property shared by the partial sums of a series does not have to be shared by the limit to which those partial sums tend. For instance, the partial sums of the series 0.3 + 0.03 + 0.003 + 0.0003 + . . . are 0.3, 0.3 + 0.03 = 0.33, 0.3 + 0.03 + 0.003 = 0.333,. . . , all of them, clearly, numbers less than 1/3; however, the limit to which those partial sums tend (that is, the sum of the original series) is 0.3333... , which is precisely the number 1/3.

2.4: On Black's Impossibility Argument

Another one of the classical arguments against the logical possibility of supertasks comes from Black (1950-51) and is constructed around the functioning of an infinity machine of his own invention. An infinity machine is a machine that can carry out an infinite number of actions in a finite time. Black's aim is to show that an infinity machine is a logical impossibility. Consider the case of one such machine whose sole task is to carry a ball from point A ($x = 0$) to point B ($x = 1$) and viceversa. Assume, in addition, that initially (at t = 12 A.M., say) the ball is at A and that the machine carries out the following infinite sequence of operations: when half the time until t* = 1 P.M. has gone by, it does the action a_1 of taking the ball from position A to position B (a_1 is thus carried out at t = 1/2 P.M.); when half the time between the performance of a_1 and t* = 1 P.M. has gone by, it does the action a_2 of taking the ball from position B to position A (a_2 is thus carried out at t = 1/2 + 1/4 P.M.); when half the time between the performance of a_2 and t* = 1 P.M. has gone by, the machine does the action a_3 of taking the ball from position A to position B (a_3 is thus performed in t = 1/2 + 1/4 + 1/8 P.M.), and so on. When we get to instant t* = 1 P.M. the machine will have carried out an infinite sequence of actions, that is, a supertask T = (a_1, a_2, a_3, . . . , a_n, . . .). The parallelism with Thomson's lamp is clear when it is realised that the ball in position A corresponds to the dim lamp and the ball in position B corresponds to the lit lamp. Nevertheless, Black believes that by assuming that at each instant the ball is either in A or else in B (and note that assuming this means that the machine transports the ball from A to B and viceversa instantaneously, but we need not be worried by this, since all that we are concerned with now is logical or conceptual possibility, not physical possibility), he can deduce, by a totally different route from Thomson's based on the symmetrical functioning of his machine, a contradiction regarding its state at t* = 1 P.M.. However, Benacerraf's criticisms also applies to Black's argument. In effect, the latter hinges on how the machine works, and as this has only been specified for instants of time previous to t* = 1 P.M., it follows that what can be logically inferred from the functioning of the machine is only applicable to those instants previous to t* = 1 P.M.. Black seeks to deduce a contradiction at t* = 1 P.M. but he fails at the same point as Thomson: whatever happens to the ball at t* = 1 P.M. cannot be a logical consequence of what has happened to it before. Of course, one can always specify the functioning of the machine for

instants t greater than or equal to 1 P.M. by saying that at all those instants the machine will not perform any actions at all, but that is not going to help Black. His argument is fallacious because he seeks to reach a logical conclusion regarding instant t* = 1 P.M. from information relative to times previous to that instant.. In the standard argument against Zeno's dichotomy one could similarly specify Achilles's position at t* = 1 P.M. saying, for instance, that he is at B ($x = 1$), but there is no way that this is going to get us a valid argument out of a fallacious one, which seeks to deduce logically where Achilles will be at t* = 1 P.M. from information previous to that instant of time.

2.5: Benacerraf's Critique and the Dichotomy Arguments

The cases dealt with above are examples of how Benacerraf's strategy can be used against supposed demonstrations of the logical impossibility of supertasks. We have seen that the strategy is based on the idea that

> (I) the state of a system at an instant t* is not a logical consequence of which states he has been in before t* (where by ‘state’ I mean ‘relevant state of the world’, see section 1.1)

and occasionally on the idea that

> (II) the properties shared by the partial sums of a series do not have to be shared by the limit to which those partial sums tend.

Since the partial sums of a series make up a succession (of partial sums), (II) may be rewritten as follows:

> (III) the properties shared by the terms of a succession do not have to be shared by the limit to which that succession tends.

If we keep (I), (II) and (III) well in mind, it is easy not to yield to the perplexing implications of certain supertasks dealt with in the literature. And if we do not yield to the perplexing results, we will also not fall into the trap of considering supertasks conceptually impossible. (III), for instance, may be used to show that it is not impossible for Achilles to perform the supertasks of the inverse and the direct dichotomy of Zeno. Take the case of the direct dichotomy: the limit of the corresponding succession of instants of time t_1, t_2, t_3, . . . at which each one of Achilles's successive sub-runs is finished can be the instant at which Achilles's supertask has been accomplished, even if such a supertask is not achieved at any one of the instants in the infinite succession t_1, t_2, t_3, . . . (all of this in perfect agreement with (III)).

2.6: Conclusion

As a corollary it may be said that supertasks do not seem to be intrinsically impossible. The contradictions that they supposedly give rise to may be avoided if one rejects certain unwarranted assumptions that are usually made. The main such assumption, responsible for the apparent conceptual

impossibility of supertasks, is that properties which are preserved after a finite number of actions or operations will likewise be preserved after an infinite number of them. But that is not true in general. For example, we saw in section 1.2 above that the relevant state of the world after the performance of a task T = $(a_1, a_2, \ldots, a_n)$ on the relevant state S was logically determined by T and by S (and was $a_n(a_{n-1}(a_{n-2}(\ldots(a_2(a_1(S)))\ldots))))$, but we have now learned that after the performance of a supertask T = $(a_1, a_2, a_3, \ldots, a_n, \ldots)$ it is not (that is the core of Benacerraf's critique). The same sort of uncritical assumptions seem to be in the origin of infinity paradoxes in general, in which certain properties are extrapolated from the finite to the infinite that are only valid for the finite, as when it is assumed that there must be more numbers greater than zero than numbers greater than 1000 because all numbers greater than 1000 are also greater than zero but not viceversa (Galileo's paradox). In conclusion, if some supertasks are paradoxical, it is not because of any inherent inconsistency of the notion of supertask. This opinion is adhered to by authors such as Earman and Norton (1996).

Section 3: On The Physical Possibility Of Supertasks

We have gone through several arguments for the conceptual impossibility of supertasks and counterarguments to these. Those who hold that supertasks are conceptually possible may however not agree as to whether they are also physically possible. In general, when this issue is discussed in the literature, by physical possibility is meant possibility in relation with certain broad physical principles, laws or ‘circumstances’ which seems to operate in the real world, at least as far as we know. But it is a well-known fact that authors do not always agree about which those principles, laws or circumstances are.

3.1: Kinematical Impossibility

In our model of Thomson's lamp we are assuming that at each moment the switch can be in just one of two set positions (‘off’, ‘on’). If there is a fixed distance d between them, then clearly, since the switch swings an infinite number of times from the one to the other from t = 12 A.M. until t* = 1 P.M., it will have covered an infinite distance in one hour. For this to happen it is thus necessary for the speed with which the switch moves to increase unboundedly during this time span. Grünbaum has taken this requirement to be physically impossible to fulfil. Grünbaum (1970) believes that there is a sort of physical impossibility of a purely kinematical nature (kinematical impossibility) and describes it in more precise terms by saying that a supertask is kinematically impossible if:

> a) At least one of the moving bodies travels at an unboundedly increasing speed,
>
> b) For some instant of time t*, the position of at least one of the moving bodies does not approach any defined limit as we get arbitrarily closer in time to t*.

It is clear then that the Thomson's lamp supertask, in the version presented so far, is kinematically (and eo ipso physically) impossible, since not only does the moving switch have to travel at a speed that increases unboundedly but also -because it oscillates between two set positions which are a constant distance d apart- its position does not approach any definite limit as we get closer to instant t* = 1 P.M., at which the supertask is accomplished. Nevertheless, Grünbaum has also shown models of Thomson's lamp which are kinematically possible. Take a look at Figure 1, in which the switch (in position 'on' there) is simply a segment AB of the circuit connecting generator G with lamp L. The circuit segment AB can shift any distance upwards so as to open the circuit in order for L to be dimmed. Imagine we push the switch successively upwards and downwards in the way illustrated in Figure 2, so that it always has the same velocity $v = 1$.

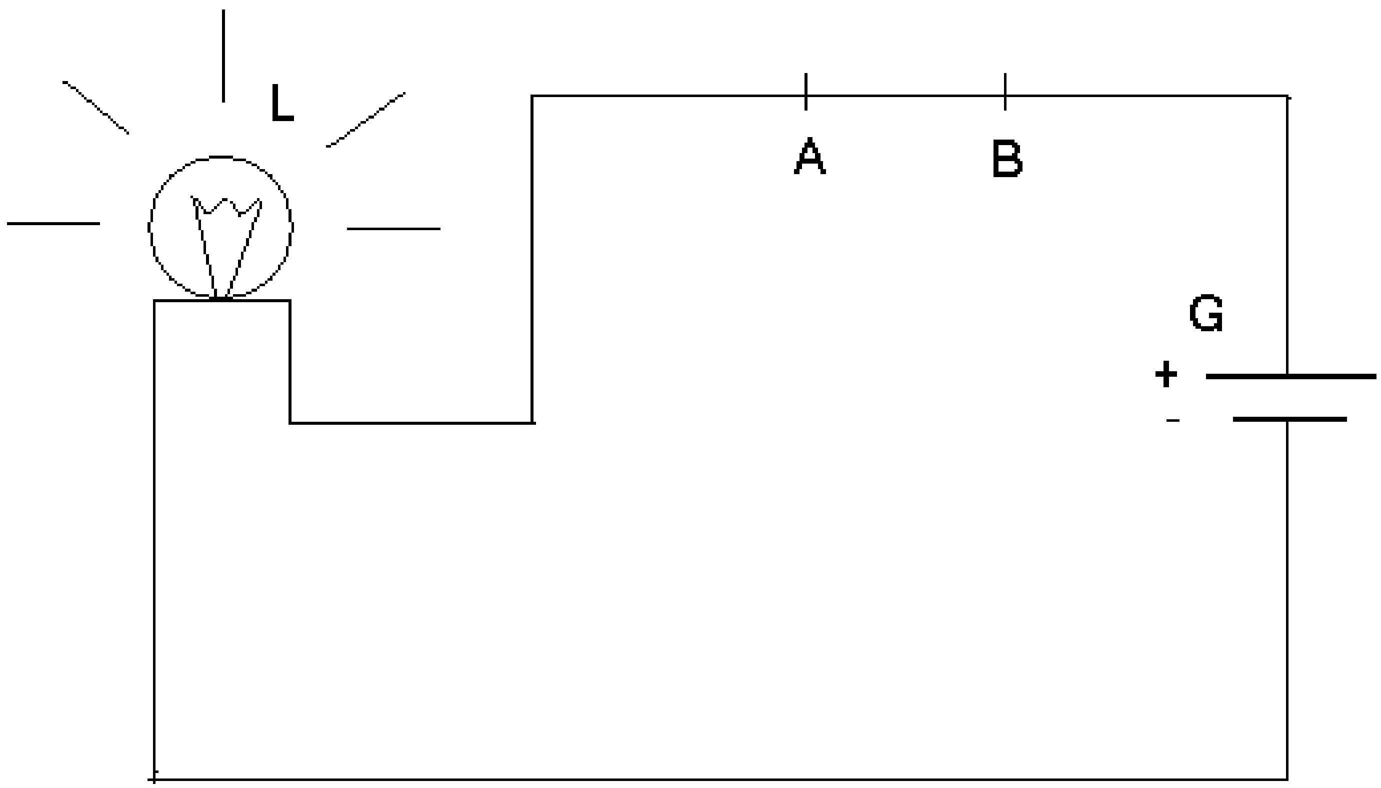

Figure 1

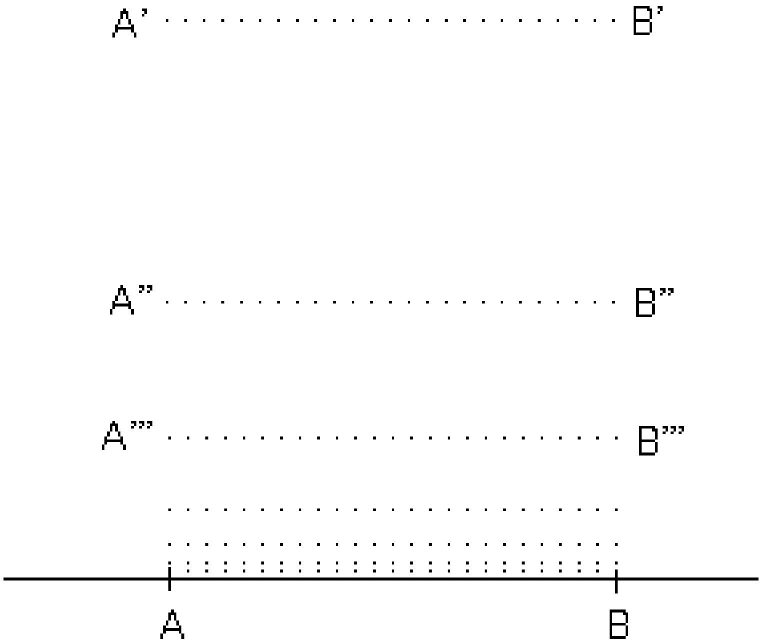

Figure 2

The procedure is the following. Initially (t = 0) the switch is in position $A'B'$ (lamp dim) a height of 0.2 above the circuit and moving downwards (at *v* = 1). At t = 0.2 it will be in position AB (lamp lit) and will begin moving upwards (*v* = 1). At t = 0.2 + 0.01 it will be in position $A''B''$ (lamp dim) and will begin moving downwards (*v* = 1). At t = 0.2 + 0.01 + 0.01 = 0.2 + 0.02 it will be in position AB (lamp lit) and will begin moving upwards (*v* = 1). At t = 0.2 + 0.02 + 0.001 it will be in position $A'''B'''$ (lamp dim), and so on. Obviously, between t = 0 and t* = 0.2 + 0.02 + 0.002 + . . . = 0.2222... = 2/9, the lamp is in the states ‘dim’ and ‘lit’ an infinite number of times, and so a supertask is accomplished. But this supertask is not kinematically impossible, because it has been so designed that the switch always moves with velocity *v* = 1 -- and, therefore, condition (a) for kinematical impossibility is not fulfilled -- and that, additionally, as we get closer to the limit time t* = 2/9 (the only one which could cause us any trouble) the switch approaches more and more a well-defined limit position, position AB (lamp lit) -and, therefore, condition b) for kinematical impossibility is not fulfilled either. Once the kinematical possibility has been established, what is the state of the lamp at t* = 2/9? What has been said so far does not enable us to give a determinate answer to this question (just as the obvious kinematical possibility of Achilles's supertask in the dichotomy paradox does not suffice to determine where Achilles will be at t* = 1 P.M.), but there exists a ‘natural’ result. It seems intuitively acceptable that the position the switch will occupy at t* = 2/9 will be position AB, and so the lamp will be lit at that instant. There is no mysterious asymmetry about this result. Figure 3 shows a model of Thomson's lamp with a switch that works according to exactly the same principles as before, but which will yield the ‘natural’ result that the lamp will in the end be dim at t* = 2/9. In effect, the switch will now finally end up in the ‘natural’ position AB at t* = 2/9 and will thereby bring about an electrical short-circuit that will make all the current in the generator pass through the cable on which the switch is set, leaving nothing for the more resistant path where the lamp is.

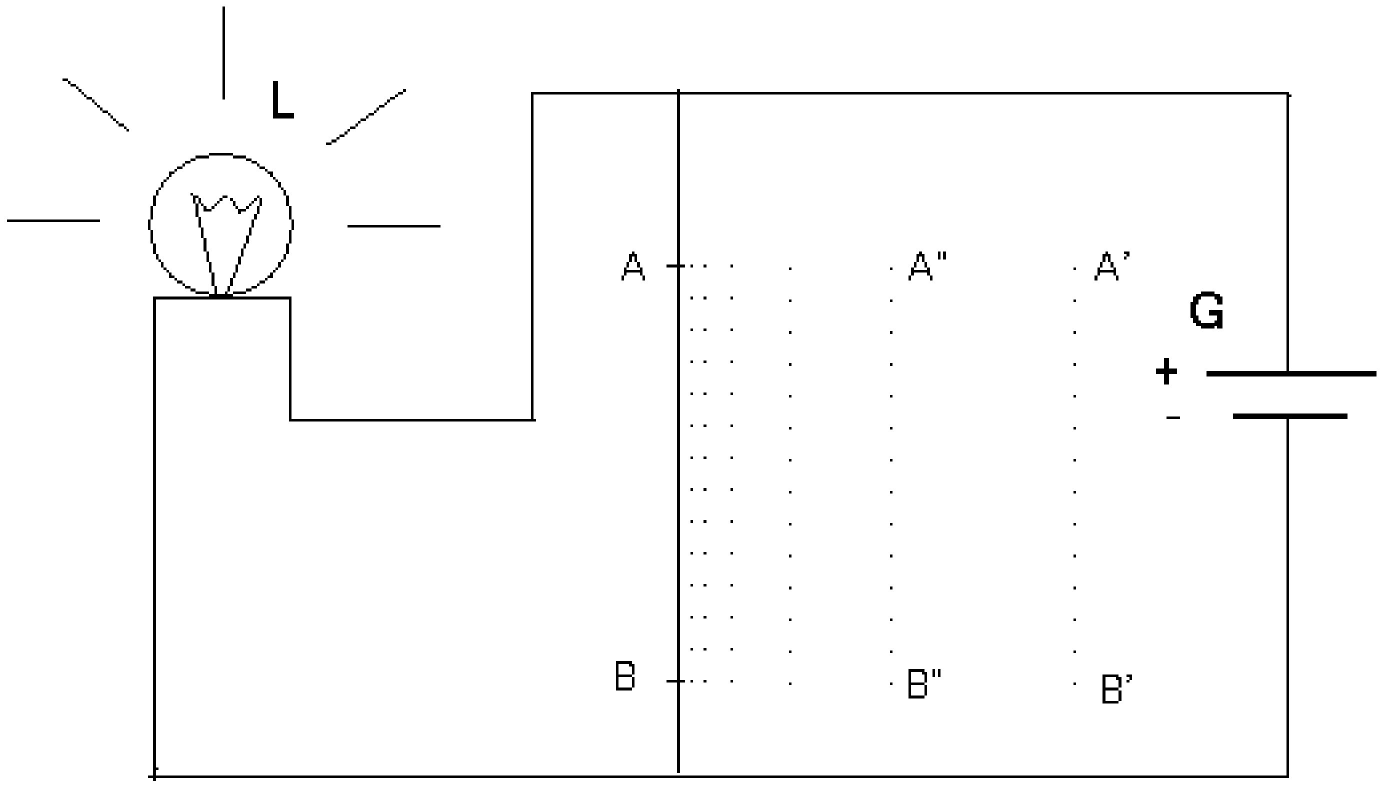

Figure 3

There are some who believe that the very fact that there exist Thomson's lamps yielding an intuitive result of ‘lamp lit’ when the supertask is accomplished but also other lamps whose intuitive result is ‘lamp dim’ brings up back to the contradiction which Thomson thought to have found originally. But we have nothing of that sort. What we do have is different physical models with different end-results. This does not contradict but rather corroborates the results obtained by Benacerraf: the final state is not logically determined by the previous sequence of states and operations. This logical indeterminacy can indeed become physical determinacy, at least sometimes, depending on what model of Thomson's lamp is employed.

A conspicuous instance of a supertask which is kinematically impossible is the one performed by Black's infinity machine, whose task it is to transport a ball from position A ($x = 0$) to position B ($x = 1$) and from B to A an infinite number of times in one hour. As with the switch in our first model of Thomson's lamp, it is obvious that the speed of the ball increases unboundedly (and so condition a) for impossibility is met), while at the same time, as we approach t* = 1 P.M., its position does not tend to any defined limit, due to the fact that it must oscillate continuously between two set positions A and B one unity distance apart from each other (and so also condition b) for impossibility is met).

3.2: The Principle Of Continuity and the Solution to the Philosophical Problem of Supertasks

Up to this point we have seen examples of supertasks which are conceptually possible and, among these, we have discovered some which are also physically possible. For the latter to happen we had to make

sure that at least some requirements were complied with which, plausibly, characterise the processes that can actually take place in our world. But some definitive statement remains to be made about the philosophical problem posed by supertasks: what the state of the world is after they have been accomplished. The principles of physical nature which have so far been appealed to do not enable us to pronounce on this matter. The question thus arises whether some new principle of a physical nature can be discovered which holds in the real world and is instrumental in answering the question what the state of the world will be after a supertask. That discovery would allow us to resolve a radical indeterminacy which still persists -the reader will remember that even in the case of Achilles's dichotomy supertask we were quite unable to prove that it would conclude with Achilles in point B ($x = 1$). In Section 2.1 we saw that such proof cannot be obtained by recourse to the mathematical theory of infinite series exclusively; why should it be assumed that this abstract theory is literally applicable to the physical universe? After all, amounts of money are added up applying ordinary arithmetic but, as Black reminded us, velocities cannot be added up according to ordinary arithmetic.

Since Benacerraf's critique, we know that there is no logical connection between the position of Achilles at t* = 1 P.M. and his positions at instants previous to t* = 1 P.M. Sainsbury [1988] has tried to bridge the gap opened by Benacerraf. He claims that this can be achieved by drawing a distinction between abstract space of a mathematical kind and physical space. No distinction between mathematical and physical space has to be made, however, to attain that goal; one need only appeal to a single principle of physical nature, which is, moreover, simple and general, namely, that the trajectories of material bodies are continuous lines. To put it more graphically, what this means is that we can draw those trajectories without lifting our pen off the paper. More precisely, that the trajectory of a material body is a continuous line means that, whatever the instant t, the limit to which the position occupied by the body tends as time approaches t coincides precisely with the position of the body at t. Moreover, the principle of continuity is highly plausible as a physical hypothesis: the trajectories of all physical bodies in the real world are in fact continuous. What matters is that we realise that, aided by this principle, we can now finally demonstrate that after the accomplishment of the dichotomy supertask, that is, at t* = 1 P.M., Achilles will be in point B ($x = 1$). We know, in fact, that as the time Achilles has spent running gets closer and closer to t* = 1 P.M., his position will approach point $x = 1$ more and more, or, equivalently, we know that the limit to which the position occupied by Achilles tends as time get progressively closer to t* = 1 P.M. is point B ($x = 1$). As Achilles's trajectory must be continuous, by the definition of continuity (applied to instant t = t* = 1 P.M.) we obtain that the limit to which the position occupied by Achilles tends as time approaches t* = 1 P.M. coincides with Achilles's position at t* = 1 P.M. Since we also know that this limit is point B ($x = 1$), it finally follows that Achilles's position at t* = 1 P.M. is point B ($x = 1$). Now is when we can spot the flaw in the standard argument against Zeno mentioned in section 2.1, which was grounded on the observation that the sequence of distances covered by Achilles (1/2, 1/2 + 1/4, 1/2 + 1/4 + 1/8, . . .) has 1 as its limit. This alone does not suffice to conclude that Achilles will reach point $x = 1$, unless it is assumed that if the distances run by Achilles have 1 as their limit, then Achilles will as a matter of fact reach $x = 1$, but assuming this entails using the principle of continuity. This principle affords us a rigorous demonstration of what, in any event, was already plausible and intuitively ‘natural’: that after having performed the infinite sequence of actions ($a_1, a_2, a_3, \ldots, a_n, \ldots$) Achilles will have reached point B ($x = 1$). In addition, now it is easy to show how, with a switch like the one in Figure 2, Thomson's lamp in Figure 1 will reach t* = 2/9 with its switch in position AB and will therefore be lit.

We have in fact already pointed out (3.1) that in this case, as we get closer to the limit time t* = 2/9, the switch indefinitely approaches a well-defined limit position -position AB. Due to the fact that the principle of continuity applies to the switch, because it is a physical body, this well-defined limit position must coincide precisely with the position of the switch at t* = 2/9. Therefore, at t* = 2/9 the latter will be in positon AB and, consequently, the lamp will be lit. By the same token, it can also be shown that the lamp in Figure 3 will be dim at time t* = 2/9.

3.3: The Postulate of Permanence

In Section 3.2, the principle of continuity helped us find the final state resulting from the accomplishment of a supertask in cases in which there exists a ‘natural’ limit for the state of the physical system involved as time progressively approaches the instant at which the supertask is achieved. Now it is considerably more problematic to apply this principle to supertasks for which there is no ‘natural’ limit. For an example, let us consider Black's infinity machine, introduced in Section 2.4, and let us ask ourselves where the ball will be at instant t* = 1 P.M. at which the supertask is achieved. We can set up a reductio ad absurdum type of argument, as follows. Assume that at t* = 1 P.M. the ball were to occupy position P, that it was in point P. According to the principle of continuity, it follows that the limit to which the position occupied by the ball tends as time approaches t* = 1 P.M. is precisely position P. We know, though, that Black's infinity machine makes the ball oscillate more and more quickly between the fixed points A ($x = 0$) and B ($x = 1$) as we get closer to t* = 1 P.M., so the position of the ball does not approach any definite limit as we get closer to t* = 1 P.M. This conclusion patently contradicts what follows from the principle of continuity. Therefore, the assumption that, after Black's supertask is achieved (t* = 1 P.M.), the ball is at point P leads to contradiction with the principle of continuity. Thus, the ball cannot be at point P at t* = 1 P.M., and as the point can be any, given that it has been chosen arbitrarily, the ball cannot be at any single one of the points, which means that at t* = 1 P.M. the ball has ceased to exist. This funny conclusion is consistent with the principle of continuity, as we have just seen, but it enters into contradiction with what could be termed the ‘postulate of permanence’: no material body (and by that we mean a given quantity of matter) can go out of existence all of a sudden, without leaving any traces. The postulate of permanence seems to characterise our world at least as evidently as the principle of continuity. Notice in particular that certain physical bodies (particles) may dematerialise, but that is not inconsistent with the postulate of permanence since such a dematerialisation leaves an energy trace (which is not true of Black's ball). Consequently, we can see that the case Black's infinity machine is one in which the principles of continuity and permanence turn out to be mutually inconsistent. As long as we do not give up any of them, we are forced to accept that such an infinity machine is physically impossible.

Section 4: The Physics of Supertasks

As we do not know exactly what laws of nature there are, it goes without saying that the question whether a particular supertask is physically possible (that is, compatible with those laws) cannot be given a definitive answer in general. What we have done in 3 above is rather to set out necessary conditions for physical possibility which are plausible (such as the principle of continuity) and sufficient conditions for

physical impossibility which are likewise plausible (such as Grünbaum's criterion of kinematical impossibility). In this section we shall look into a problem related to the one just dealt with, but one to which a definitive answer can be given: the problem of deciding whether a certain supertask is possible within the framework of a given physical theory, that is, whether it is compatible with the principles of that theory. These are two distinct problems. At this stage our object are theories whereas in 3 above we were concerned with the real world. What we are after is supertasks formulated within the defined framework of a given physical theory which can tell us something exciting and/or new about that theory. We will discover that this search will lead us right into the heart of basic theoretical problems.

4.1: A New Form of Indeterminism: Spontaneous Self-Excitation

Classical dynamics is a theory that studies the motion of physical bodies which interact among themselves in various ways. The vast majority of interesting examples of supertasks within this theory have been elaborated under the assumption that the particles involved only interact with one another by means of elastic collisions, that is, collisions in which no energy is dissipated. We shall see here that supertasks of type *w** give rise to a new form of indeterministic behaviour of dynamical systems. The most simple type of case (Pérez Laraudogoitia [1996]) is illustrated by the particle system represented in Figure 4 at three distinct moments. It consists of an infinite set of identical point particles P_1, P_2, P_3, . . . , P_n, . . . arranged in a straight line. Take the situation depicted in Figure 4A first. In it P_1 is at one unity distance from the coordinate origin O, P_2 at a distance 1/2 of O, P_3 at a distance 1/3 of O and so on. In addition, let it be that all the particles are at rest, except for P_1, which is approaching O with velocity v = 1. Suppose that all this takes place at t = 0. Now we will employ

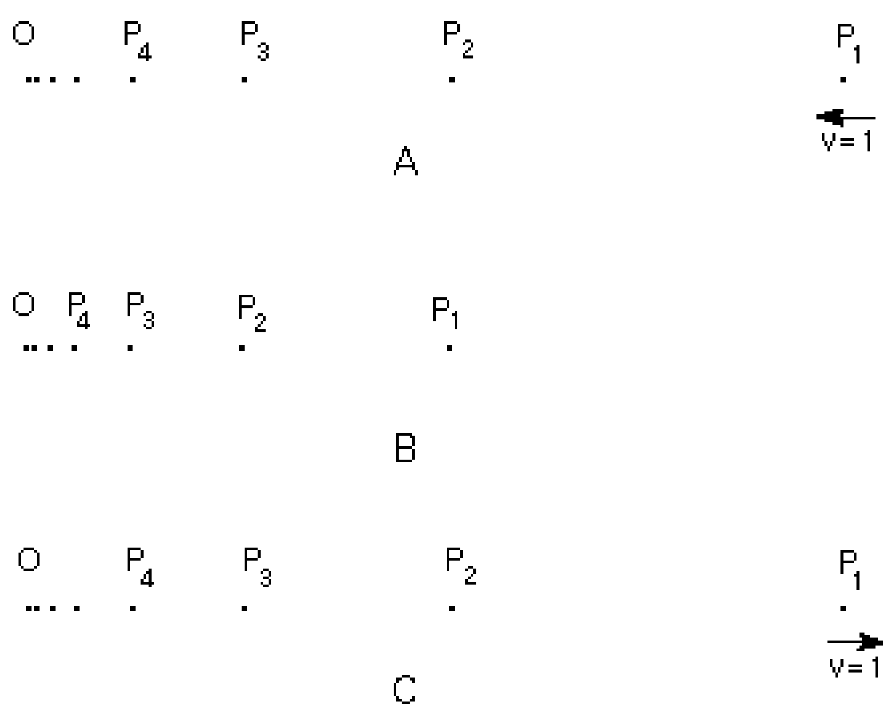

Figure 4

the well-known dynamic theorem by which if two identical particles undergo an elastic collision then

they will exchange their velocities after colliding. If our particles P_1, P_2, P_3, . . . collide elastically, it is easy to predict what will happen after t = 0 with the help of this theorem. In the event that P_1 were on its own, it would reach O at t = 1, but in fact it will collide with P_2 and lie at rest there, while P_2 will acquire velocity $v = 1$. If P_1 and P_2 were on their own, then it would be P_2 that would reach O at t = 1, but P_2 will in fact collide with P_3, and lie at rest there, while P_3 will acquire velocity $v = 1$. Again, it can be said that if P_1, P_2 and P_3 were on their own, then it is P_3 that would reach O at t = 1, but in actual fact it will collide with P_4 and lie at rest there, while P_4 will acquire velocity $v = 1$, and so on. From the foregoing it follows that no particle will get to O at t = 1, because it will be impeded by a collision with another particle. Therefore, at t = 1 all the particles will already lie at rest, which yields the configuration in Figure 4B. Since P_1 stopped when it collided with P_2, it will occupy the position P_2 had initially (at t = 0). Similarly, P_2 stopped after colliding with P_3 and so it will occupy the position P_3 had initially (at t = 0), . . . , etc. If we view each collision as an action (which is plausible, since it involves a sudden change of velocities), it turns out that between t = 0 and t = 1 our evolving particle system has performed a supertask of type *w*. The second dynamic theorem we will make use of says that if a dynamic process is possible, then the process resulting from inverting the direction in which all the bodies involved in it move is also possible. Applying this to our case, if the process leading from the system in the situation depicted in Figure 4A to the situation depicted in Figure 4B is possible (and we have just seen it is), then the process obtained by simply inverting the direction in which the particles involved move will also be possible. This new possible process does not bring the system from configuration 4B back to configuration 4A but rather changes it into configuration 4C (as the direction in which P_1 moves must be inverted). As the direct process lasts one time unity (from t = 0 to t = 1), so will the inverse process, and as in the direct process the system performs a supertask of type *w*, in the inverse process it will perform one of type *w**. What is interesting about this new supertask of type *w**? What's interesting is that it takes the system from a situation (4B) in which all its component particles are at rest to another situation (4C) in which not all of them are. This means that the system has self-excited, because no external influence has been exerted on it, and, what is more, it has done so spontaneously and unpredictably, because the supertask can set off at any instant and there is no way of predicting when it will happen. We have found a supertask of type *w** to be the source of a new form of dynamical indeterminism. The reason we speak of indeterminism is because there is no initial movement to the performance of the supertask. The system self-excites in such a way that each particle is set off by a collision with another one, and it is the ordinal type *w** of the sequence of collisions accomplished in a finite time that guarantees movement, without the need for a ‘prime mover’. Now movement without a ‘prime mover’ is precisely what characterises the dynamical indeterminism linked to supertasks of type *w**.

4.2: Bifurcated Supertasks

Within relativity theory, supertasks have been approached from a radically different perspective from the one adopted here so far. This new perspective is inherently interesting, since it links the problem of supertasks up with the relativistic analysis of the structure of space-time. To get an insight into the nature of that connection, let us first notice that, according to the theory of relativity, the duration of a process will not be the same in different reference systems but will rather vary according to the reference system

within which it is measured. This leaves open the possibility that a process which lasts an infinite amount of time when measured within reference system O may last a finite time when measured within a different reference system O'.

The supertask literature has needed to exploit space-times with sufficiently complicated structure that global reference systems cannot be defined in them. In these and other cases, the time of a process can be represented by its ‘proper time’. If we represent a process by its world-line in space-time, the proper time of the process is the time read by a good clock that moves with the process along its world-line. A familiar example of its use is the problem of the twins in special relativity. One twin stays home on earth and grows old. Forty years of proper time, for example, elapses along his world-line. The travelling twin accelerates off into space and returns to find his sibling forty years older. But much less time -- say only a year of proper time -- will have elapsed along the travelling twin world-line if he has accelerated to sufficiently great speeds.

If we take this into account it is easily seen that the definition of supertask that we have been using is ambiguous. In section 1 above we defined a supertask as an infinite sequence of actions or operations carried out in a finite interval of time. But we have not specified in whose proper time we measure the finite interval of time. Do we take the proper time of the process under consideration? Or do we take the proper time of some observer who watches the process? It turns out that relativity theory allows the former to be infinite while the latter is finite. This fact opens new possibilities for supertasks. Relativity theory thus forces us to disambiguate our definition of supertask, and there is actually one natural way to do it. We can use Black's idea -- presented in 2.4 -- of an infinity machine, a device capable of performing a supertask, to redefine a supertask as an infinite sequence of actions or operations carried out by an infinity machine in a finite interval of the machine's own proper time measured within the reference system associated to the machine. This redefinition of the notion of supertask does not change anything that has been said until now; our whole discussion remains unaffected so long as ‘finite interval of time’ is read as ‘finite interval of the machine's proper time’. This notion of supertask, disambiguated so as to accord with relativity theory, will be denoted by the expression ‘supertask-1’. Thus:

> Supertask-1: an infinite sequence of actions or operations carried out by an infinity machine in a finite interval of the machine's proper time.

However we might also imagine a machine that carries out an infinite sequence of actions or operations in an infinite machine proper time, but that the entire process can be seen by an observer in a finite amount of the observer's proper time.

It is convenient at this stage to introduce a contrasting notion:

> Supertask-2: an infinite sequence of actions or operations carried out by a machine in a finite interval of an observer's proper time.

While we did not take relativity theory into account, the notions of supertask-1 and supertask-2

coincided. The duration of an interval of time between two given events is the same for all observers. However in relativistic spacetimes this is no longer so and the two notions of supertasks become distinct. Even though all supertasks-1 are also supertasks-2, there may in principle be supertasks-2 which are not supertasks-1. For instance, it could just so happen that there is a machine (not necessarily an infinity machine) which carries out an infinite number of actions in an interval of its own proper time of infinite duration, but in an interval of some observer's proper time of finite duration. Such a machine would have performed a supertask-2 but not a supertask-1.

The distinction between supertasks-1 and supertasks-2 is certainly no relativistic hair-splitting. Why? Because those who hold that, while conceptually possible, supertasks are physically impossible (this seems to be the position adopted by Benacerraf and Putnam [1964], for instance) usually mean that supertasks-1 are physically impossible. But from this, it does not follow that supertasks-2 must also be physically impossible. Relativity theory thus adds a brand-new, exciting extra dimension to the challenge presented by supertasks. Earman and Norton (1996), who have studied this issue carefully, use the name ‘bifurcated supertasks’ to refer specifically to supertasks-2 which are not supertasks-1, and I will adopt this term.

4.3: Bifurcated Supertasks and the Solution to the Philosophical Problem of Supertasks

What shape does the philosophical problem posed by supertasks -- introduced in Section 1.2 -- take on now? Remember that the problem lay in specifying the set of sentences which describe the state of the world after the supertask has been performed. The problem will now be to specify the set of sentences which describe the relevant state of the world after the bifurcated supertask has been performed. Before this can done, of course, the question needs to be answered whether a bifurcated supertask is physically possible. Given that we agree that compatibility with relativity theory is a necessary and sufficient condition of physical possibility, we can reply in the affirmative.

Pitowsky (1990) first showed how this compatibility might arise. He considered a Minkowski spacetime, the spacetime of special relativity. He showed that an observer O* who can maintain a sufficient increase in his acceleration will find that only a finite amount of proper time elapses along his world-line in the course of the complete history of the universe, while other unaccelerated observers would find an infinite proper time elapsing on theirs.

Let us suppose that some machine M accomplishes a bifurcated supertask in such a way that the infinite sequence of actions involved happens in a finite interval of an observer O's proper time. If we imagine such an observer at some event on his world-line, all those events from which he can retrieve information are in the ‘past light cone’ of the observer. That is, the observer can receive signals travelling at or less than the speed of light from any event in his past light cone. The philosophical problem posed by the bifurcated supertask accomplished by M has a particularly simple solution when the infinite sequence of actions carried out by M is fully contained within the past light cone of an event on observer O's world-line. In such a case the relevant state of the world after the bifurcated supertask has been performed is M's

state, and this, in principle, can be specified, since O has causal access to it. Unfortunately, a situation of this type does not arise in the simple bifurcated supertask devised by Pitowsky (1990). In his supertask, while the accelerated observer O* will have a finite upper bound on the proper time elapsed on his world-line, there will be no event on his world-line from which he can look back and see an infinity of time elapsed along the world-line of some unaccelerated observer.

To find a spacetime in which the philosophical problem posed by bifurcated supertasks admits of the simple solution that has just been mentioned, we will move from the flat spacetime of special relativity to the curved spacetimes of general relativity. One type of spacetime in the latter class that admits of this simple solution has been dubbed Malament-Hogarth spacetime, from the names of the first scholars to use them (Hogarth [1992]). An example of such a spacetime is an electrically charged black hole (the Reissner-Nordstroem spacetime). A well known property of black holes is that, in the view of those who remain outside, unfortunates who fall in appear to freeze in time as they approach the event horizon of the black hole. Indeed those who remain outside could spend an infinite lifetime with the unfortunate who fell in frozen near the event horizon. If we just redescribe this process from the point of view of the observer who does fall in to the black hole, we discover that we have a bifurcated supertask. The observer falling in perceives no slowing down of time in his own processes. He sees himself reaching the event horizon quite quickly. But if he looks back at those who remain behind, he sees their processes sped up indefinitely. By the time he reaches the event horizon, those who remain outside will have completed infinite proper time on their world-lines. Of course, the cost is high. The observer who flings himself into a black hole will be torn apart by tidal forces and whatever remains after this would be unable to return to the world in which he started.

Section 5: What Supertasks Entail for the Philosophy of Mathematics

5.1: A Critique of Intuitionism

The possibility of supertasks has interesting consequences for the philosophy of mathematics. To start with, take a well-known unsolved mathematical problem, for example that of knowing whether Goldbach's conjecture is or is not correct. Goldbach's conjecture asserts that any even number greater than 2 is the sum of two prime numbers. Nobody has been capable of showing whether this is true yet, but if supertasks are possible, that question can be resolved. Let us, to that effect, perform the supertask of type *w* consisting in the following sequence of actions: action a_1 involves checking whether the first pair greater than 2 (number 4) is the sum of two prime numbers or not; let this action be accomplished at t = 0.3 P.M.; action a_2 involves checking whether the second pair greater than 2 (number 6) is the sum of two prime numbers or not; let this action be accomplished at t = 0.33 P.M.; action a_3 involves checking whether the third pair greater than 2 (number 8) is the sum of two prime numbers or not; let this action be accomplished at t = 0.333 P.M., and so on. It is clear that at t = 0.33333... = 1/3 P.M., the instant at which the supertask has already been performed, we will have checked all the pairs greater than 2, and, therefore, will have found some which is not the sum of two prime numbers or else will have found all of

them to be the sum of two prime numbers. In the first case, we will know at t = 1/3 P.M. that Goldbach's conjecture is false; in the seocnd case we will know at t = 1/3 P.M. that it is true. Weyl (1949) seems to have been the first to point to this intriguing method -the use of supertaks- for settling mathematical questions about natural numbers. He, however, rejected it on the basis of his finitist conception of mathematics; since the performance of a supertask involves the successive carrying out of an actual infinity of actions or operations, and the infinity is impossible to accomplish, in his view. For Weyl, taking the infinite as an actual entity makes no sense. Nevertheless, there are more problems here than Weyl imagines, at least for those who ground their finitist philosophy of mathematics on intuitionism à la Brouwer. That is because Brouwer's rejection of actual infinity stems from the fact that we, as beings, are immersed in time. But this in itself does not mean that all infinities are impossible to accomplish, since an infinity machine is also ‘a being immerse in time’ and that in itself does not prevent the carrying out of the infinity of successive actions a supertask is comprised of. It goes without saying that one can adhere to a constructivist philosophy of mathematics (and the consequent rejection of actual infinity) for diferent reasons from Brouwer's; supertasks will still not be the right kind of objet to study either.

As Benacerraf and Putnam (1964) have observed, the acknowledgement that supertasks are possible has a profound influence on the philosophy of mathematics: the notion of truth (in arithmetic, say) would no longer be doubtful, in the sense of dependent on the particular axiomatisation used. The example mentioned earlier in connection with Goldbach's conjecture can indeed be reproduced and generalised to all other mathematical statements involving numbers (although, depending on the complexity of the statement, we might need to use several infinity machines instead of just one), and so, consequently, supertasks will enable us to decide on the truth or falsity of any arithmetical statement; our conclusion will no longer depend on provability in some formal system or constructibility in a more or less strict intuitionistic sense. This conclusion seems to lead to a Platonist philosophy of mathematics.

5.2: The Importance of the Malament-Hogarth Spacetime

A similar conclusion follows regarding the implications of supertasks for the philosophy of mathematics if one only accepts the possibility of bifurcated supertasks. Of course, a bifurcated supertask performed in a non-Malament-Hogarth space-time would not be so interesting in this sense. The obvious reason is that we would not even have a sound procedure to determine the truth or falsity of Goldbach's conjecture seen in 5.1 by means of the performance of an infinite sequence of actions of order type w. To really have a safe decision procedure in this simple case (as in other, more complex ones) there must necessarily exist an instant of time at which it can be said that the supertask has been accomplished. Otherwise, in the event that the machine finds a counterexample to Goldbach's conjecture we will know it to be false, but in the event of the machine finding none we will not be able to tell that it is true, because for this there must exist an instant of time by which the supertask has been accomplished and at which we can say something like: "the supertask has been performed and the machine has found no counterexamples to Goldbach's conjecture; therefore, the conjecture is true". It follows that, in the case of a bifurcated supertask, possessing a sound decision procedure on Goldbach's conjecture requires the existence of an observer O such that the infinite sequence of actions (of order type w) carried out by the machine lies within the past light cone of an event on observer O's world-line. But this is equivalent to saying that the

relativistic space-time in which the bifurcated supertask is performed is a Malament-Hogarth space-time, and this realisation is one of the main reasons why this sort of relativistic space-times have been studied in the literature.

Note, finally, the intuitionistic criticism of the possibility of supertasks is even less effective in the case of bifurcated supertasks, because in this latter case it is not required that there is any sort of device capable of carrying out an infinite number of actions or operations in a finite time (measured in the reference system associated to the device in question, which is the natural reference system to consider). In contrast, from the possibility of bifurcated supertasks in Malament-Hogarth space-times strong arguments follow against an intuitionistic philosophy of mathematics. As Earman and Norton remind us, it is noteworthy that certain facts relative to the non-Euclidean structure of space-time can have relevant consequences for the nature of mathematical truth.

Determinates vs. Determinables

Everything red is colored, and all squares are polygons. A square is distinguished from other polygons by being four-sided, equilateral, and equiangular. What distinguishes red things from other colored things? This has been understood as a conceptual rather than scientific question. Theories of wavelengths and reflectance and sensory processing are not considered. Given just our ordinary understanding of color, it seems that what differentiates red from other colors is only redness itself. The Cambridge logician W. E. Johnson introduced the terms determinate and determinable to apply to examples such as red and colored. Chapter XI, of Johnson's Logic, Part I (1921), “The Determinate and the Determinable,” is the main text for discussion of this distinction.

This entry consists of the following sections. Section 1 attends closely to Chapter XI, of W. E. Johnson's Logic, Part I. Section 2 briefly discusses Johnson's use of the determinate-determinable relation elsewhere than Chapter XI of Logic, Part I, and connects this with A. N. Prior, “Determinables, Determinates, and Determinants” (1949). Section 3 describes a 1959 symposium between Stephan Körner and John Searle entitled “On Determinables and Resemblance” and examines both contributions critically. Section 4 describes the Munsell Color Solid so that color examples can be more exact. Section 5 describes and criticizes attempts to define the determinate-determinable relation by means of predicate entailment in the style of Searle. Section 6 pays more attention to this distinction and directs attention to a certain understanding of “disjunctive predicate.” Contrived disjunctive and conjunctive predicates are the typical cause of difficulties in attempts to define the determinate-determinable relation. Section 7 distinguishes independent predicates from non-independent predicates, and thus distinguishes disjunctive and conjunctive predicates from non-disjunctive and non-conjunctive predicates, in a way that assumes no prior classifications of determinates under a determinable. Section 8 explores a view advanced by Johnson and endorsed by many others that the things in *the* world, as distinguished from our descriptions and conceptions of them, are absolutely determinate. This section entertains the contrary view that nothing is absolutely determinate.

1. W. E. Johnson's Chapter on The Determinable

1.1 Substantive and Adjective

Johnson invents phrases and also attaches new meanings to familiar words. His terms determinate, determinable, occurrent, continuant and ostensive definition have entered the philosophical lexicon. Some of his innovations are largely forgotten. Throughout Logic and especially throughout Part I, Chapter XI, Johnson uses a distinction between substantive and adjective. Although he draws and observes many distinctions meticulously, the distinction between the mention of a linguistic expression and its use is not among them. Adjective and substantive sometimes appear in his writings to be linguistic items. More often they are definitely non-linguistic. They are logical categories, “the ultimate comprising classes” (1922, p. 60). “My distinction between substantive and adjective is roughly equivalent to the more popular philosophical antithesis between particular and universal; the notions, however, do not exactly coincide” (1922, p. xiii). The term ‘adjective’ remains in all forthcoming quotations from Johnson. In discussion of Johnson, the term ‘property’ often replaces ‘adjective’ although it is not an exact equivalent.

Johnson is interested in the logical differences between ‘Red is a colour’ and ‘Plato is a man’. He says that the second sentence involves adjectival predication. ‘Human’ is an adjective (property) predicated of Plato. ‘Colour,’ on the other hand, is not an adjective (property) predicated of red (1921, p. 176).

1.2 Similarity and Difference

Color is one of Johnson's central examples. Red and blue are determinate with respect to the determinable color, and Carolina Blue and Duke Blue are determinate with respect to blue.

> The relation of a determinate to its determinable resembles that of an individual to a class, but differs in some important respects. For instance, taking any given determinate, there is only one determinable to which it can belong. Moreover, any one determinable is a literal summum genus not subsumable under any higher genus; and the absolute determinate is a literal infima species under which no other determinate is subsumable. (Part I, Introduction, 1921, p. xxxv)

What makes red and blue and Carolina Blue all colors? Johnson denies that there is some property [some “secondary” adjective] that red and blue share that makes them both colors. The view that color is itself a property that red and blue share requires an explanation of what distinguishes the color red from the color blue. Explanations such as “Red is the color of fire trucks” and “Blue is the color of my true love’s eyes” miss the point. They refer to mere contingent facts. An appropriate explanation should provide a necessary truth such as ‘Triangles are three-sided polygons.’

Rather than resemblance, the sharing of some property, that make red and blue colors, says Johnson, it is

differences between colors.

> In fact, the several colours are put into the same group and given the same name colour, not on the ground of any partial agreement, but on the ground of the special kind of difference which distinguishes one colour from another; whereas no such difference exists between a colour and a shape. (1921, p. 176)

The absence of a difference or exclusion of this kind explains why red and square is not a determinate of a single determinable. “Taking any given determinate, there is only one determinable to which it can belong” (1921, p. xxxv). The nature of the exclusion also explains why no two determinates of the same determinable can qualify exactly the same entire spatio-temporal part of any object (1921, p. 181).

Arguments about the incompatibility of colors in the 1950s and 1960s were concerned with theories of necessity, analyticity, the *a priori*, and meaning. (Edwards and Pap, 1973, has a bibliography of such works, pp. 745-746.) These discussions rarely address specifically the relation between determinables and determinates. Nor do assumptions about the incompatibility of determinates often connect with the problem of understanding incompatibility in general. When the problem of incompatibility reopens there may be less emphasis on philosophy of language and logic and more emphasis on the branch of metaphysics that studies the nature of properties and the recently formed hybrid of metaphysics and science that studies the nature of color and other sensory qualities.

1.3 Determinables and Genera

Treatments of the determinate-determinable relation often contrast it with the species-genus relation. Features such as three-sided differentiate the species triangle under the genus polygon, while the only feature that distinguishes the determinate red under the determinable color is the very determinate itself. A genus-species relation obtains when a proper definition of the form $X = YZ$ is possible. When no such definition is possible and certain other formal requirements are satisfied, the determinable-determinate relation obtains. For this neat, sharp contrast, Johnson provides at best only equivocal support. His remarks are sometimes incompatible with this contrast.

Consider Johnson's examples. The introduction of the term ‘determinable’ in Chapter XI reads: “I propose to call such terms as colour and shape determinables in relation to such terms as red and circular which will be called determinates” (1921, p. 174). So circular is a determinate of the determinable shape despite the existence of a proper definition that distinguishes circles from other shapes. Different shapes are incompatible and are therefore under the same determinable. Being related by incompatibility (in the right way) appears to be necessary and sufficient for items to be determinates under a single determinable. Some determinates such as red cannot be differentiated by a traditional, conjunctive genus-species definition. Others such as square and circular can be so differentiated. Johnson's example of shape shows that a determinable-determinate relation does not require the impossibility of a conjunctive definition.

Rather than insist on a sharp contrast, Johnson attempts to subsume traditional species-genus relations under determinate-determinable relations:

> We have now to point out that the increased determination of adjectival predication which leads to a narrowing of extension may consist—not in a process of conjunction of separate adjectives—but in the process of passing from a comparatively indeterminate adjective to a comparatively more determinate adjective under the same determinable. Thus there is a genuine difference between that process of increased determination which conjunctivally introduces foreign adjectives, and that other process by which without increasing, so to speak, the number of adjectives, we define them more determinately.
>
> In fact, the foreign adjective which appears to be added on in the conjunctive process, is really not introduced from the outside, but is itself a determinate under another determinable, present from the start, though suppressed in the explicit connotation of the genus. (Johnson, 1921, pp. 178-9)

Johnson goes on to provide a symbolic representation of botanical classification in which there are five determinables. One of these determinables is number of cotyledons under which fall the determinates acotyledon, monocotyledon, and dicotyledon. The other determinables concern stamens, the corolla, forms of attachment, and divisibility. The determinables in this botanical example represent “the summum genus ‘plants’ as describable under these five heads” (1921, p. 180). A determinable can have several dimensions.

Johnson's discussion of color variations illustrates such dimensions. Colors vary according to hue, saturation and brightness, and these variations are independent of one another. If hue, saturation, and brightness are determinables, they are not separate, since they depend on each other. There cannot be saturation without hue, for example, even though no determination of saturation requires any particular determination of hue. Johnson says that the determinable color is “single, though complex, in the sense that the several constituent characters upon whose variations its variability depends are inseparable” (1921, p. 183).

There is a difficulty here because the dependence patterns between the three variables are not entirely uniform. Hue and saturation cannot exist without each other, or without brightness, but degrees of brightness do not require either hue or saturation. Black and white movies and photographs and many other achromatic examples come to mind. Dimensions of quality space can vary in their dependence relations on each other.

1.4 Quality Order

There are differences between determinates under the same determinable. Johnson says these differences are comparable. The difference between red and yellow, for example, is greater than that between red and orange.

> In this case the several determinates are to be conceived as necessarily assuming a certain serial order, which develops from the idea of what may be called ‘adjectival betweenness.’ The term ‘between’ is used here in a familiar metaphorical sense imagined most naturally in spatial form. (1921, pp. 181-182)

The three-place relation (*Dabc*) *the difference between a and c is greater than that between a and b,* however, does not by itself provide an adequate definition of ‘between.’ A diagram helps to illustrate this point. Assume for the purpose of diagramming that *the difference between a and c* specifies a certain distance in quality

space. A circle with center *a* and radius *ac* represents points in the space at distance *ac* from point *a*. Any distance between point *a* and any point *b* within this circle is less than the distance between *a* and *c*. A point *b* within this circle represents *Dabc*. As Figure 1 illustrates, *Dabc* is consistent with the distance between *b* and *c* being greater than the distance between *a* and *c*.

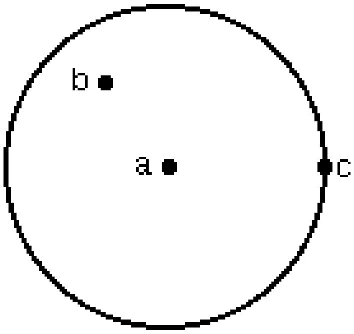

Figure 1

In this situation, *b* is not between *a* and *c* in any sense. For example, the difference (or distance) between red and yellow is greater than the distance between red and purplish red, but purplish red is not between red and yellow.

The word ‘betwixt’, which appears in the next paragraph, comes from Goodman (1951), pp. 244-253, but only the word, not Goodman's definition or intended sense. This is an occasion to remark that Goodman and Carnap (1928) develop constructions of quality order much more elaborate than Johnson's. They do not use a primitive equivalent to *Dabc* in their constructions. Johnson returns to questions of quality order in Part II of Logic, Chapter VII, “The Different Kinds of Magnitude.”

The following conjunctive definition, which overcomes this particular difficulty, is not a revision of a formulation by Johnson. It is the beginning, rather, of a brief attempt to define betweenness by means of Johnson's primitive *Dabc*: Let us say that *b* is betwixt *a* and *c* if and only if *Dabc* and *Dcba*. Orange, but not reddish purple, is betwixt red and yellow. Figure 2 adds to the circle in figure 1 another circle with the same radius with point *c* in the middle. A point *b* betwixt *a* and *c* is within the intersection of these two circles.

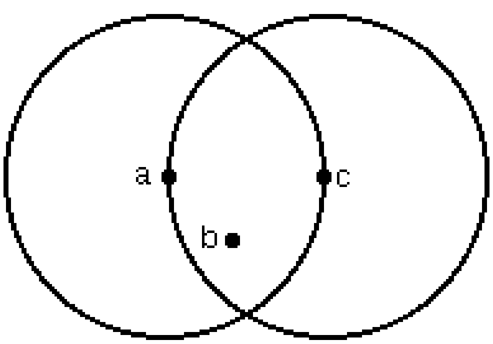

Figure 2

Betwixtness is too wide a notion to explicate betweenness. Suppose that the points in Figure 3, a specification of Figure 2, stand for the following colors:

R: a fully saturated, bright sample of red

Y: a fully saturated, bright sample of yellow

O_1: a fully saturated, bright sample of orange

O_2: a less saturated, less bright sample of orange

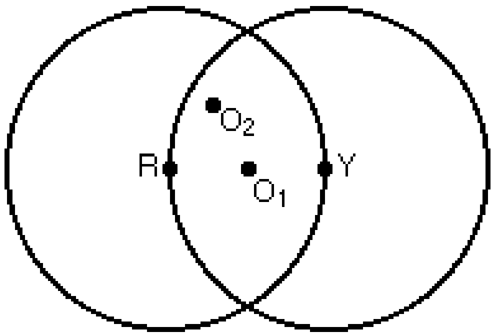

Figure 3

O_1 and O_2 are both betwixt R and Y. But it is natural to represent O_1 as 'right between' R and Y. O_2 is somewhat off to the side. A better definition of 'between' will count O_1 but not O_2 as between R and Y.

Relying again on the notion of *distance*, one can distinguish two senses of *between*. (1) *B* is *somewhere between A* and *C* if and only if the distance between *A* and *B* plus the distance between *B* and *C* is equal to the distance between *A* and *C*. That is, *B* is located somewhere on the straight line (in Euclidean space) between *A* and *B*. (2) *B* is *exactly* or *halfway between A* and *B* if and only if *B* is somewhere between *A* and *C* and also the distance between *A* and *B* is equal to the distance between *B* and *C*. The following definition, built on Johnson's primitive, attempts to define *somewhere between* in sense (1):

> *b* is somewhere between *a* and *c* if and only if *b* is betwixt *a* and *c*, and nothing is both betwixt *a* and *b* and betwixt *b* and *c*.

When two circles with no interior points in common are tangent, the point in common is on the straight line segment between the two centers. Any point on a straight line segment between points *x* and *y* is the point in common between two circles with centers *x* and *y* that have no interior points in common. As Figure 4 illustrates, *b* is on *a* straight line segment between *a* and *c* if and only if the circle *ab* is tangent to the circle *cb*. This is the case if and only if nothing is betwixt *a* and *b* and also betwixt *b* and *c*; for any such thing has to be both an interior point of circle *ab* and an interior point of circle *cb*, and these circles have no interior points in common.

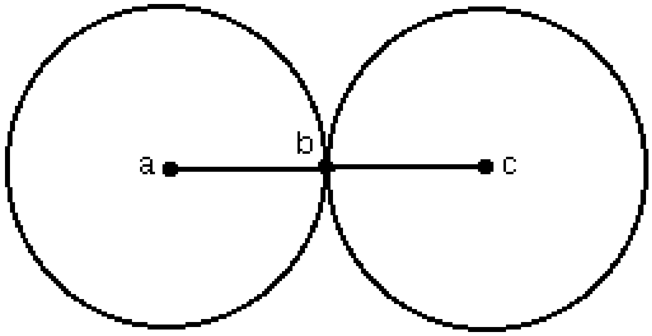

Figure 4

Figure 5, illustrates a point *b* that is betwixt *a* and *c* but is not situated like point *b* in Figure 4. In this case, point *b* is on the intersection of two circle that have interior points in common. Figure 5 shows this region as a shaded area. Anything within this shaded area is both betwixt *a* and *b* and betwixt *b* and *c*.

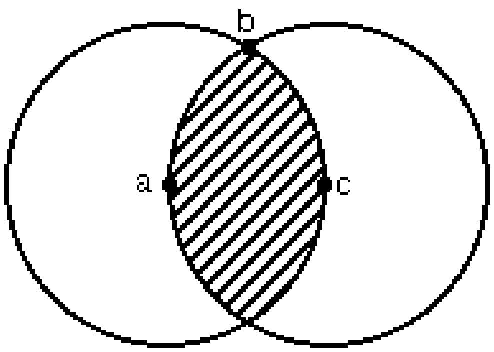

Figure 5

Although a distance between points in these diagrams can be equal, or double, or half, another distance between points, that is due to the conventions of drawing these diagrams. There has been no explication of these distance notions by means of the primitive *Dabc*. A definition of *right between* would provide a sufficient condition for the equality of the distance between *a* and *b* and the distance between *b* and *c*, but there is no attempt here to provide such a definition using only the primitive *Dabc*.

Johnson uses his notion of betweenness to draw two independent distinctions between quality order, interminable series in contrast with cyclic, and continuous series in contrast with discrete (1921, pp. 182-183). His use of the three-place relation *the difference between a and c is greater than that between a and b* undermines a point he insists on earlier that resemblance between determinates does not group them under a determinable. Johnson's three-place relation can also be expressed *the similarity between a and b is greater than that between a and c*. Comparisons between differences are also comparisons between likenesses or similarities. Perhaps his point can be expressed as follows: no two-place relation of resemblance groups determinates under a determinable, although a three-place relation can be useful for this purpose. Johnson's chapter ends with the pronouncement that "The practical impossibility of literally determinate characterization must be contrasted with the universally adopted postulate that the characters of things which we can only characterize more or less indeterminately, are, in actual fact, absolutely determinate" (1921, p. 185). Section 8 examines this claim.

2. W. E. Johnson and A. N. Prior

Johnson discuses determinates and determinables in Parts II and III of Logic (1922, 1924) and also elsewhere in Part I. In Part I, in a chapter entitled “Laws of Thought,” Johnson formulates four principles of adjectival determination that correspond to four more familiar principles of propositional determinations such as ‘Not both *P* and not-*P*’ and ‘Either *P* or not-*P*.’

In Part III, Johnson is concerned primarily with induction and causation. Throughout Part III, he distinguishes the ‘occurrent’ from the ‘continuant’ and often discusses change, cause, and continuants with reference to determinates of determinables.

In Part II, Johnson refers to determinables in several different contexts. One discussion is especially important for understanding Prior's later treatment of the topic. Johnson introduces the notion of a structural proposition which he compares to “what Kant meant by ‘analytic’” (1922, pp. 14-15). In a structural proposition, “it is impossible to realise the meaning of the subject-term without implicitly conceiving it under that category” (1922, p. 15).

Arthur N. Prior takes up the question of structural propositions that relate determinates to determinables in the two-part article “Determinables, Determinates, and Determinants” (Prior, 1949).

> Since a subject's being in a certain universe or category, i.e., its being determinable in certain ways, is presupposed in every genuine characterization of it, an assertion that it is in this category, and is thus determinable, would have for its predicate something which cannot really be separated from the subject in order to be predicated of it. (Prior, 1949, p. 18)

Prior's article reveals his very wide-ranging knowledge of the history of logic. The article together with Prior (1955), reflects a detailed knowledge of Johnson's entire logical system, not only the three-part Logic (1921, 1922, 1924), but also Johnson (1892). Although some of the topics in Prior (1949) have not prompted much subsequent discussion in connection with determinates and determinables, Prior puts his finger on one theme that is now central.

> The problem of fitting the relation between determinates and determinables into a purely “conjunctional” logic might be summarily described as the problem of justifying the inference from “This is red” to “This is coloured” on the assumption that all formal inference consists in the passage from a conjunction to one of its conjuncts. (Prior, 1949, pp. 191-192)

As mentioned earlier, there seems to be no conjunction of the proper kind of the form ‘*x* is *F* and *x* is colored’ that is equivalent to ‘*x* is red.’ Examples of improper conjunctions are:

> *x* is red and *x* is colored,
> *x* is either red or not colored, and *x* is colored.

3. The Körner-Searle Symposium

The 1959 Joint Session of the Aristotelian Society and the Mind Association included a symposium "On Determinables and Resemblance" in which Stephan Körner spoke first and John Searle spoke second.

Körner presents a logic of inexact concepts which reappears in his 1966 book Experience and Theory. This logic recognizes, in addition to traditional set members and non-members, intermediate or neutral set members. Two overlapping sets are related by exclusion-overlap if, by stipulating of each neutral candidate that it is either positive or negative, it is possible to end up with two overlapping sets and it is possible to end up with two sets related by exclusion (Körner, 1966, pp. 45-46. This clarifies or revises Körner, 1959, pp. 127-128). He gives blue and green as examples to illustrate exclusion overlap. Blue and green (strictly, the set of blue things and the set of green things) are not absolutely exact; they have neutral candidates. Since nothing is a member of the green set and also a member of the blue set, these sets exclude each other. When each neutral candidate is converted by stipulation either to a member or to a non-member, the two adjusted sets may still exclude each other, because no neutral candidate has been designated both green and blue, or if there is at least one formerly neutral candidate that is now both green and blue, the adjusted sets overlap.

Körner claims that determinates under the same determinable are linked, directly or indirectly, by exclusion-overlap. Red and green are not directly related by exclusion overlap, but they are presumably related indirectly by direct links between red and orange, orange and yellow, yellow and yellowish green, yellowish green and green. The concepts of red and green are therefore linked. Concepts are linked if and only if they are related by exclusion overlap or the ancestral of exclusion overlap (1959. pp. 130-131). Concepts *P* and *Q* are fully linked if and only if every species of *P* is linked with every species of *Q* (1959, p. 131). Full linkage is crucial to Körner's treatment of determinates and determinables.

Körner attempts to explain the determinate-determinable relation by means of full linkage. He asserts that full linkage is a stronger relation than mere linkage. It is difficult, however, to be convinced that this is true. If at least one species of *P* is linked to at least one species of *Q*, and all the species of *P* are linked to each other, as are all the species of *Q*, then every species of *P* is linked with every species of *Q*, and *P* and *Q* are fully linked. Körner claims that 'angry,' a species of 'yellow or angry,' is not linked with 'green.' This would be an interesting and important result, if true. Körner here identifies a problem that occupies subsequent discussions. How are we to distinguish ordinary predicates such as 'green' from disjunctive predicates such as 'yellow or angry'?

It appears that on Körner's own definitions, 'green' and 'yellow' are linked, 'yellow' is linked to 'yellow or angry,' and 'yellow or angry' is linked to 'angry,' so 'green' is linked to 'angry.' Until explanations are forthcoming how one or more of these alleged linkages violate Körner's requirements, the main influence of his contribution is to direct attention to the problem of disjunctive predicates.

John Searle makes a fresh start. In his attempt to explicate the determinate-determinable relation, he uses the notion of predicate entailment. In the standard sense, entailment is a relation between items, such as propositions, that have truth-values. Searle extends this notion to a relation between predicates. 'Red' entails 'colored' because it is impossible for something to be red and not colored. This is a natural extension, and others have adopted it. Indeed, talk of predicate entailment leads easily to talk of property entailment: the property red entails the property colored.

Searle and others who follow him draw a sharp distinction between the determinate-determinable relation and

the genus-species relation. (He repeats this distinction in Searle, 1967.) The definition of a species is by means of genus and differentia, which are logically independent. (Predicates *F* and *G* are independent when none of the following entailments hold: *F* entails *G*, *G* entails *F*, *F* entails not-*G*, and not-*F* entails *G*.) A determinate of a determinable cannot be defined in this way, by a conjunction of independent predicates. A traditional (although inadequate) definition ‘Man is a rational animal’ passes the genus/differentia test. ‘Rational’ and ‘animal’ are independent terms. The attempted definition ‘Red is a color that is red’ does not pass because ‘red’ entails ‘colored.’

There are both historical and logical difficulties with this view.

The genus-species relation is an ancient philosophical topic. No crisp, clear definition can be consistent with everything that has been said before. Searle's confident exposition, however, contradicts some standard views. A logic text in wide use for many decades gives the following as a rule of definition:

> The better the definition, the more completely will the differentia be something that can only be conceived as a modification of the genus: and the less appropriately therefore will it be called a mere attribute of the subject defined. (Joseph, 1916, p. 112)

Aristotle mentions differentia that entail the genus, as in ‘Walking animal’ (Topics, IV. 6) and ‘Footed animal’ (Metaphysics, Z. 12). In his Commentary on Z. 12, Bostock says that the first differentia should entail the genus (Aristotle, 1994, pp. 176-184). Other philosophers have adopted Searle's proposal, so it is evidently attractive. It does not represent a consensus of earlier writers.

The nature of conjunction poses a logical problem for Searle's account of species. If two conjunctions are logically equivalent, it does not follow that the conjuncts of one are logically equivalent to the conjuncts of the other. The forthcoming example concerns conjunctive propositional functions about pure numbers. It is easy to construct parallel examples about mass, length, temperature, years of service, taxable income, and so on.

> *Ax*: x is greater than 4 but less than 7
> *Bx*: *x* is greater than 4 but less than 6.
> *Cx*: *x* is greater than 5 but less than 7.
> *Dx*: *x* is less than 6.
> *Ex*: *x* is greater than 5.
> *Fx*: *Bx* & *Cx*.
> *Gx*: *Dx* & *Ex*.
> *Hx*: *Bx* & *Ex*.
> *Ix*: *Cx* & *D*x.

The last four predicates, *Fx*, *Gx*, *Hx*, and *Ix*, are equivalent, so they entail the same predicates and are entailed by the same predicates. They all entail *Ax*, and *Ax* entails none of them. Their conjuncts, by design, have various entailment relations. Both conjuncts of *Fx* entail *Ax*. Neither conjunct of *Gx* entails *Ax*. One conjunct of *Hx* and of *Ix* entails *Ax* and the other conjunct in each case does not.

Searle says that “a species is a conjunction of two logically independent properties—the genus and the

differentia" (1959, p. 143). Does he mean (a) that every conjunction equivalent to the species satisfies this requirement or (b) that at least one conjunction satisfies the requirement? Stipulation (a) is too difficult to satisfy, for any species is equivalent to the conjunction of itself and the genus. Stipulation (b) is too easy to satisfy, as will be shown next. The following predicates continue the numerical example:

> *Jx*: *x* is greater than 5 but less than 6.
> *Kx*: *Jx* or (*x* is greater than 2 but less than 3).
> *Lx*: *Ax* & *Kx*.

Jx and *Lx* are equivalent to each other and also to *Fx*, *Gx*, *Hx*, and *Ix*. If we consider *Ax* to be the genus, then *Lx* is a conjunction of the genus and a term *Kx* logically independent of the genus. One can perform a trick of the same kind with the standard example of color. Consider the following contrived 'genus and differentia' definition of *red* as a species of the genus *colored*:

> x is red $=_{df}$ (x is colored) & (x is red or x is not colored).

Searle's distinction between genus-species and determinate-determinable requires some principled way of excluded disjunctive predicates such as '*Kx*' and '*x* is red or *x* is not colored.' Explaining the determinate/determinable relation requires this anyway, whether or not accepts Searle's views about the relation of species to genus.

Searle attempts to define the determinate-determinable relation and to eliminate hybrid, cross-type conjunctive and disjunctive predicates by using only the relation of predicate entailment. When a predicate A entails a predicate *B*, but *B* does not entail *A*, Searle says that *A specifies B* (1959, p. 145). *A* is a non-conjunctive specifier of *B* if and only if *A* specifies *B* and there is no pair of terms *C* and *D* such that *A* is equivalent to (entails and is entailed by) the conjunction of *C* and *D*, *C* specifies *B*, *D* does not entail *B*, and not-*D* does not entail *B*. Take the letters *A*, *B*, *C*, and *D* as abbreviations for some new predicates:

> *A*: red
> *B*: colored
> *C*: colored but not green
> *D*: red or (not colored and not prime)

A specifies *B*. There are terms *C* and *D* such that *A* is equivalent to (*C* & *D*), *C* specifies *B*, *D* does not specify *B*, and not-*D* does not specify *B*. So according to this definition, red is not a non-conjunctive specifier of colored, a result that is opposite to what Searle intends. He says that a necessary condition of *A*s being a determinate of *B* is that *A* is a non-conjunctive specifier of *B*. Like everyone who addresses this topic, Searle takes the relation between red and colored to be a paradigm of the determinate-determinable relation.

Searle adds another condition with the intention of excluding disjunctive predicates such as 'yellow or angry.' A determinate of a determinable must not only be a non-conjunctive specifier of the determinable, it must be logically related to all other non-conjunctive specifiers of the determinable. Suppose that the definition of 'non-conjunctive specifier' can be emended somehow to allow red as a non-conjunctive specifier of colored. The new requirement of logical independence wrecks the project once again because it eliminates colored as a

determinable. Consider darkish red to darkish orange. Darkish red to darkish orange and red are not logically related. Some things are both; some are neither; some are the first but not the second; some are the second but not the first. So Searle's requirements again disqualify his paradigm. (A similar objection occurs in Sanford, 1970, pp. 162-163.)

4. The Munsell Color Solid

In order to construct more exact color examples, this entry will begin to specify colors by reference to the Munsell Color Solid and will use the color designations in the Inter-Society Color Council-National Bureau of Standards (ISCC-NBS) system (see Kelly and Judd, 1976, and the entry “Color” in Webster's Third Unabridged Dictionary). These standard color designation names such as **deep yellow** and **dark grayish yellow** are hereafter printed in boldface. There are 267 names in all, and a number from 1 to 267 is associated with each name. Although the context usually makes it clear when we are talking about (mentioning) a word and when we are using the word to talk about what the word is about, the difference between bold face and the ordinary font will also observe the customary use/mention distinction. The predicate **deep yellow** refers to the color deep yellow.

Any pair of surface color that the human eye can distinguish with respect to any color dimension, hue, brightness, or saturation (chroma), corresponds to a pair of points in The Munsell Color Solid. Estimates of the number of distiguishable colors range from two million to five million. For all practical purposes, one can regard the Munsell Color Solid as a continuum of colors. Pictures of the Munsell Color Solid, however, often depict the whole solid as contstructed out of 267 blocks of uniform determinate color (as in the color plates in Webster's Third or the Adobe Technical Guide to the Munsell Color System). These standard color names are ambiguous between determinate and determinable. For each of the 267 regions in the color solid, there is a determinate representative color, the ‘center of gravity’ or centroid color. These are the colors of the Centroid Color Chips that science and commerce use to standardize color descriptions of minerals, paint, dye, ink, plastic, and so forth. **Pale yellow** is both the name of a determinate centroid color and a determinable color. The scientists who construct the color solid regard the determinable use as primary.

> There are many pairs of easily distinguishable colors which receive in this system the same designation, while there are also many pairs that can scarcely be distinguished which receive different designations. This property is, of course, an unavoidable result of dividing the color solid into an arbitary number of blocks, one for each of the 267 designations. Analogous disadvantages result for identifying the time of events according to date; two events occurring on the same date may be separated by many hours, but on the other hand two scarcely separable midnight events may have to be assigned different dates (Kelly and Judd, 1976. p. 4).

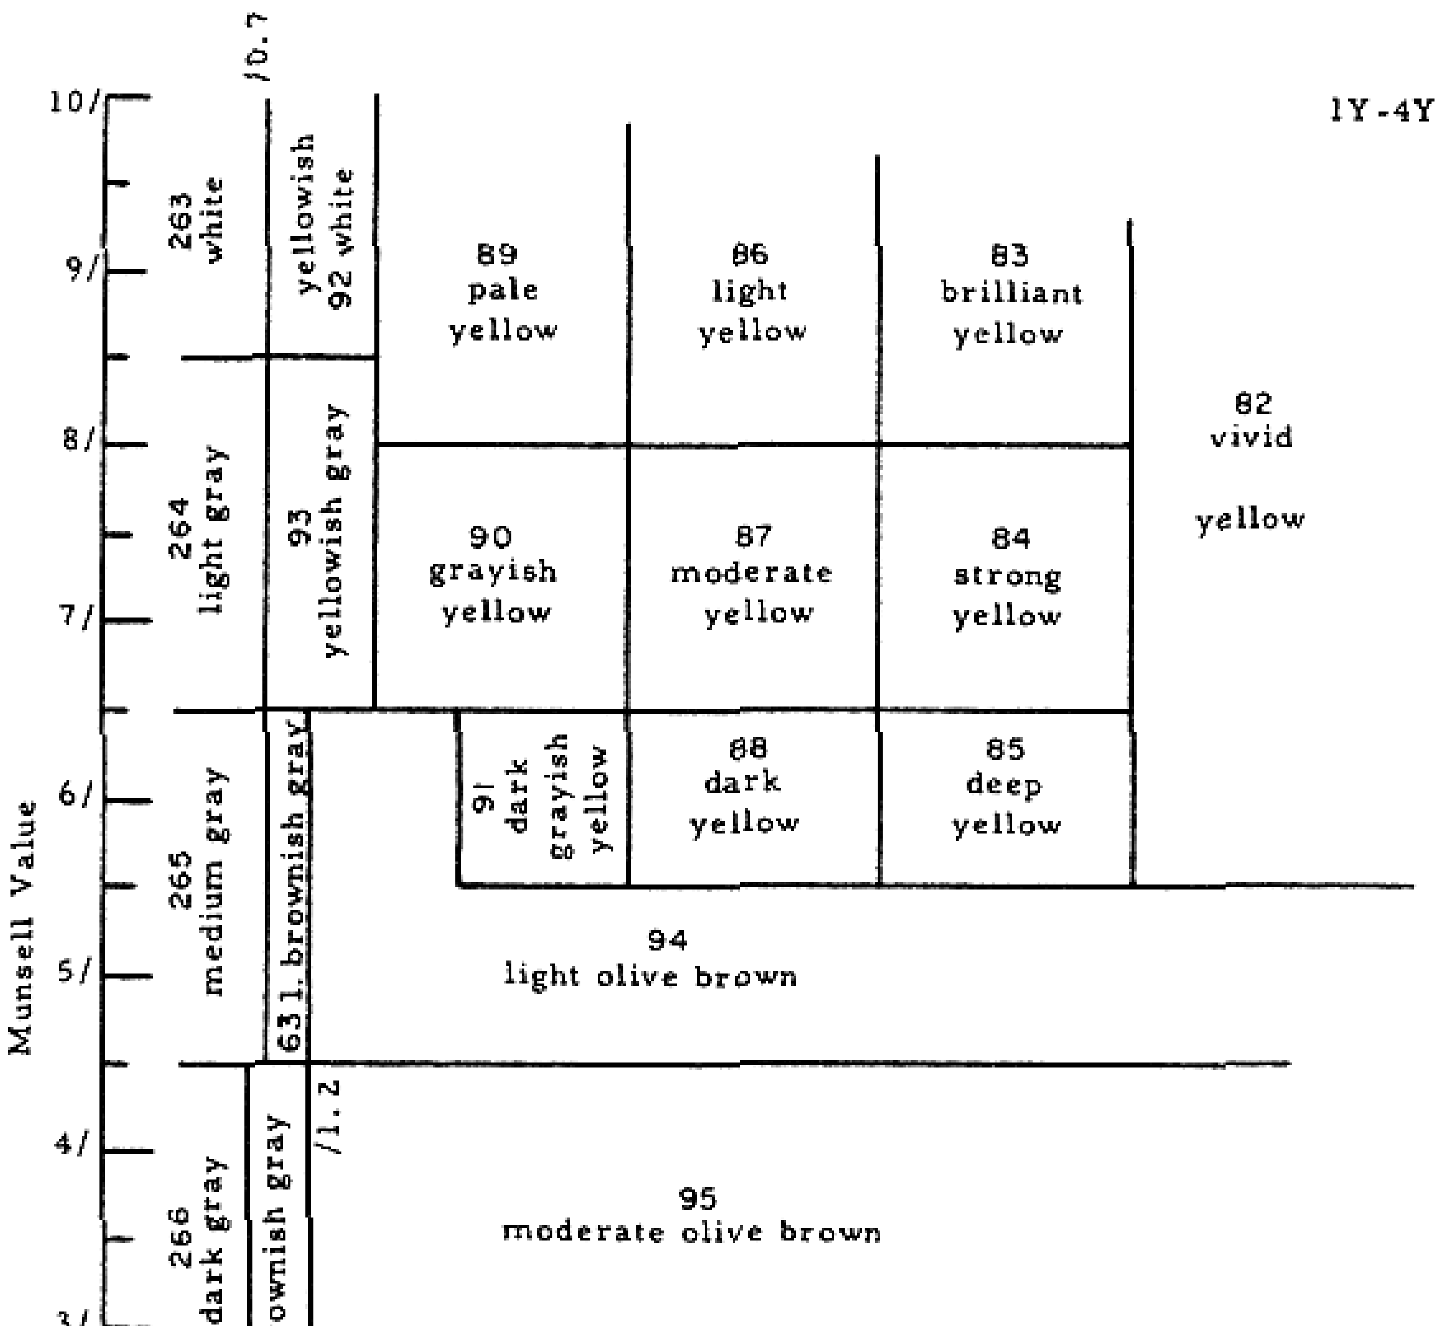
In all the forthcoming uses of the Munsell color names, they should be understood as names of determinables rather than determinates. There are distinguishable instances of pale yellow and some of these pairs are more easily distinguished than some pairs in which one color is pale yellow and the other is grayish yellow.

The bold face of the standard names contrasts in this entry with the upper case italics of invented names defined by means of the standard names. Some forthcoming definitions have the following pattern:

> *WEAK YELLOW*: **pale yellow** or **grayish yellow** (89 or 90)
>
> *ROBUST YELLOW*: **strong yellow** or **moderate yellow** or **grayish yellow** (84 or 87 or 90).

In the color solid, the regions corresponding to *WEAK YELLOW* and *ROBUST YELLOW* are as compact as any of the standard regions. These color names are as comprehensible as the standard names although, of course, they are more determinable. Weak yellow and robust yellow overlap because anything that is grayish yellow is both weak yellow and robust yellow. Neither entails the other.

Kelly and Judd contains thirty-one color charts (not themselves printed in color) that represent cross sections of the Color Solid. The vertical axis represents lightness (Munsell Value), and the horizontal axis represents saturation (Munsell Chroma). All colors that are not on the black-gray-white lightness axis have the same hue. Figure 6 is a reproduction of a chart for yellow (Kelly and Judd, 1976, p. 22) that represents the relation between pale yellow, grayish yellow, and other colors.



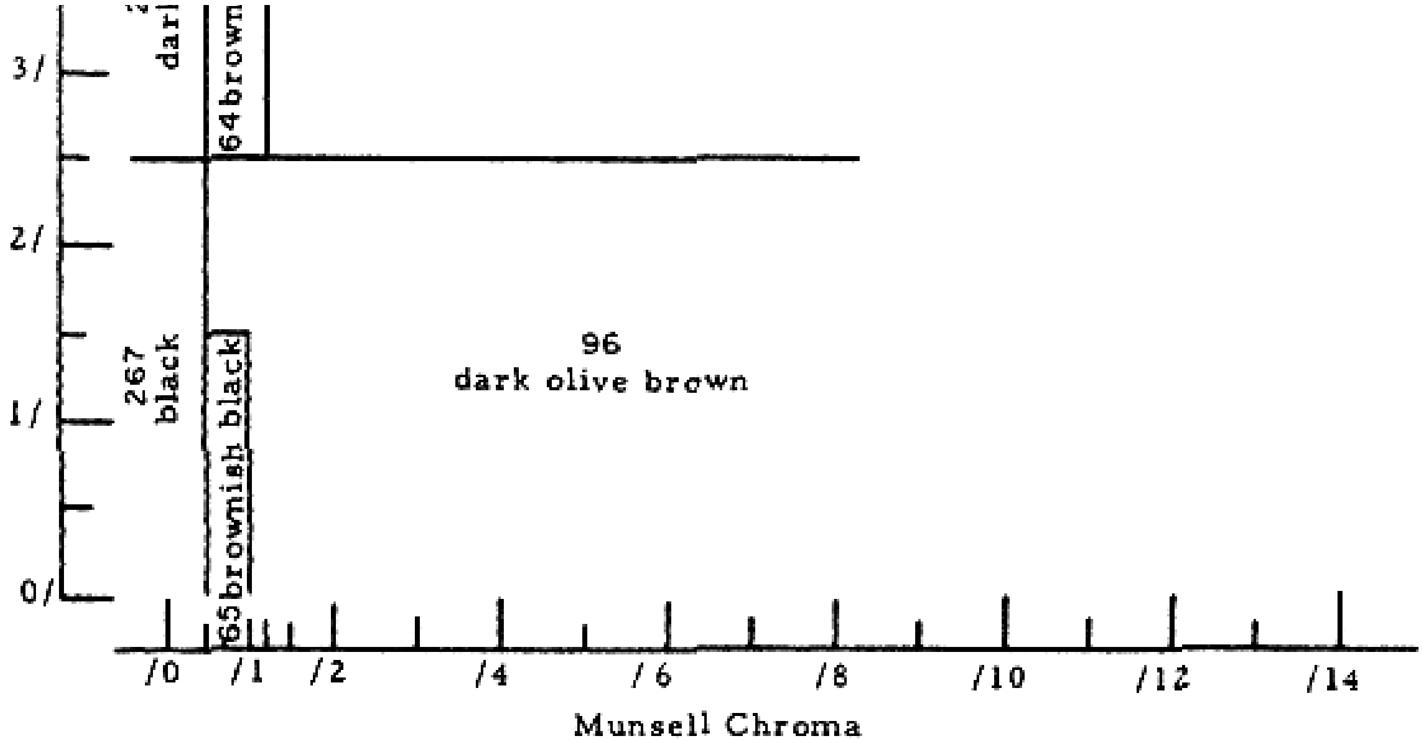


Figure 6

5. After Searle

John Woods attempts to improve Searle's definitions in “On Species and Determinates” (Woods, 1967). As Richmond Thomason demonstrates with a remorseless barrage of difficulties, Woods's efforts only make things worse, if this is possible (Thomason, 1969). Woods's requirements for determinables have, for example, the unwelcome consequence that if *Gx* is a determinable, *Gx* is a theorem of predicate logic (Thomason, 1969, pp. 95-96).

Without offering a rigorous proof, Thomason offers the opinion that the overall project of defining species-genus and determinate-determinable in terms only of entailment and negation is doomed. He proceeds “to search for an abstract, structural characterization” (p. 97) and finds an appropriate structure in the algebraic theory of semi-lattices. The resulting elegant theory is probably useful to theorists who develop taxonomic schemes. It does not, however, appear to help with the problems that Körner and Searle confront. What disqualifies colored or rectangular as a determinable of red? What disqualifies red and square as a determinate of colored?

Besides proposing lattice-theoretic requirements for natural kinds. Thomason recommends a principle of disjointness (D) (p. 98) for taxonomic systems that can be stated as follows:

> (D) If two natural kinds *a* and *b* of a taxonomic system share at least one member, then every member of *a* is a member of *b*, or every member of *b* is a member of *a*.

The two kinds *red* and *darkish red or darkish orange* fail to satisfy (D). They cannot both be natural kinds of the same taxonomic system. The algebraic theory of semi-lattices by itself provides no reason for favoring one

or the other or neither as a natural kind. Many systems of classification appear not to accord with (D). In systems of biological, physical, and chemical taxonomy, its enforcement appears arbitrary. These considerations also undermine Johnson's claim that “Taking any given determinate, there is only one determinable to which it can belong” (Johnson, 1921, p. xxxv, quoted above in Section 1.A).

Although one may nevertheless attempt to respect principle (D), it is important to realize that not every system that respects (D) divides the color solid into natural kinds. Here is another definition in terms of Munsell classification:

> *BELLOW*: **pale yellow** or **deep blue** (89 or 179).

Something pale yellow can change to grayish yellow by continuously becoming a little bit darker and without changing at all in hue or saturation and without occupying regions in the color solid other than 89 or 90. Nothing pale yellow can change to deep blue in the same way. Either the change is discontinuous or the thing occupies many regions other than 89 and 179. The predicate **pale yellow or dark blue** (*BELLOW*) is a disjunction of two determinate predicates but does not itself correspond to a determinate. **Pale yellow or grayish yellow** (*WEAK YELLOW*) is determinable with respect to its disjuncts and is a suitable determinate of ‘colored.’ Disjunctive or conjunctive syntactic forms by themselves are unreliable guides to naturalness or being a proper determinate or determinable

Dean Zimmerman has also suggested improvements to Searle's treatment of determinables. He uses, in addition to the notion of predicate or property entailment, the notion of the Boolean part of a property.

> *F* is a determinate falling under determinable $G =_{df}$ (1) *F* implies *G*, but *G* does not imply *F*; (2) there is no property *H* such that: (a) *G*&*H* implies *F* but (b) neither *H* nor not-*H* implies *G*; (3) every Boolean part of *F* implies *G*; and (4) for every property *I* such that *I* and *G* satisfy the preceding three clauses, *F* and *I* stand in some logical relation. (Zimmerman, 1997, p. 464)

How does this definition fare for our paradigm, ‘*F* (red) is a determinate falling under determinable *G* (colored)’?

Clause (3) requires that every Boolean part of the property red implies the property of being colored. From Zimmerman's discussion (1997, pp. 462-463), it is not obvious whether red has a proper Boolean part or whether its only Boolean part is red itself. Whatever the answer, clause (3) seems to be satisfied for this example. Questions remain, however, about parts of color properties. If the predicate ‘robust yellow’ stands for a property, are strong yellow, moderate yellow, and grayish yellow its Boolean parts? Or is the property of being robust yellow somehow distinct from the properties of being strong or moderate or grayish yellow? On the understanding of ‘disjunctive predicate’ to be recommended below, ‘robust yellow’ is disjunctive if and only if ‘strong or moderate or grayish yellow’ is also disjunctive. An account of disjunctive predicates, in this sense, could be useful in identifying Boolean parts of properties. An appeal to the existence or non-existence of such parts to explain disjunctiveness, on the other hand, appears to assume what it purports to establish.

Clause (1) of the definition above is satisfied and (2), unfortunately, is unsatisfied. Consider the following property:

> *H*: *red or* (*not-colored and square*)

G&*H* implies *F*, that is, *Colored* and (*red or* (*not-colored and square*)) implies *red*. *H* does not imply *G*, that is, *red or* (*not-colored and square*) does not imply *colored*. Not-*H* does not imply *G*, that is, *not-red and* (*colored or not-square*) does not imply *colored*. Zimmerman's formulation does not repair a difficulty in Searle's, namely, that the red-colored paradigm fails to satisfy the definition of the determinate-determinable relation. Predicate *H*, to be sure, is a hideous monstrosity that stands for something stapled together from Boolean parts of unrelated properties. A goal of the definitional enterprise is to distinguish ordinary, healthy predicates from such monstrosities. So we cannot assume the distinction in order to draw the distinction.

Clause (4) had difficulties of its own. Assign a new meaning to the letter '*F*':

> *F*: weak yellow

F satisfies clause (1). Pretend *F* also satisfies some revised and improved version of clause (2). Clause (3) does not stand in the way. But as one would expect, something is lurking in the wings:

> *I*: robust yellow

I satisfies clauses (1), (2), and (3) as well as *F*. But *I* and *F* are logically unrelated. All the following are possible: not-*F* and not-*I*, *F* and not-*I*, *I* and not-*F*, and *F* and *I*. An example of the kind that thwarts Searle also impedes Zimmerman.

6. Predicates and Properties

Philosophical discussion often slides back and forth between talk of predicates and talk of properties. Some philosophers suggest that there is an important logical difference between disjunctive predicates, on the one hand, and disjunctive properties or universals, on the other.

In a brisk Introduction to his early book *Problems of Mind and Matter*, in a section entitled "Generic and Specific," John Wisdom says:

> The fact is *red and hard* and *red or hard* are not universals; for strictly there are no conjunctive or disjunctive universals but only conjunctive and disjunctive facts. "This is red or hard" means "Either this is red or this is hard." (Wisdom, 1963, p. 31)

D. M. Armstrong says something very similar about disjunctive properties (1978, p. 19-23). (Armstrong is willing to admit conjunctive properties.) A disjunction of property predicates such as 'red' and 'hard' is not itself a disjunctive property predicate. There is no property of being red or hard although the disjuncts of the meaningful predicate 'red or hard' do (or might) correspond to the properties red and hard.

At this point the following distinction is relevant:

1. For some property predicates *F* and *G*, the compound predicate *F or G* is not itself a property predicate.

2. For all property predicates *F* and *G (*that do not necessarily have the same extension*)*, the compound predicate *F or G* is not itself a property predicate.

A metaphysician of properties can accept (1) or not. Accepting (2) is not an option. (2) is unacceptable. Armstrong writes:

> Disjunctive properties offend against the principle that a genuine property is identical in its different particulars. Suppose *a* has a property *P* but lacks *Q*, while *b* has *Q* but lacks *P*. It seems laughable to conclude from these premisses that *a* and *b* are identical to some respect. Yet both have the “property”, *P or Q*. (1978, p. 20)

Something that satisfies the first disjunct of the following predicate need not be identical to or resemble in any relevant respect something that satisfies the second disjunct: ‘More than ten million miles from Memphis or sings “All of Me” off key.’ This example is intended to be a disjunction of laughably unrelated components. Not every predicate of the form *P or Q* is good for a laugh in this way.

Perhaps there is no current consensus about the accepted meanings to the technical phrases ‘disjunctive predicate’ and ‘conjunctive predicate.’ If that is so, then the following principles are useful suggestions for fixing their meanings, 'a' stands here for 'acceptable' and 'u' stands for 'unacceptable':

> (Conj-a) If predicates *F* and *G* are equivalent (necessarily apply to the same things), then *F* is conjunctive if and only if *G* is also conjunctive.
>
> (Disj-a) If predicates *F* and *G* are equivalent, then *F* is disjunctive if and only if *G* is also disjunctive.

On the other hand, it is useful to reject both the following principles:

> (Conj-u) If *F* is equivalent to a predicate of the form *K and L*, then *F* is conjunctive.
>
> (Disj-u) If *F* is equivalent to a predicate of the form *K or L* then *F* is disjunctive.

According to (Conj-u) and (Disj-u), all predicates are both conjunctive and disjunctive. Even redundant predicates such as *F and F* and *F or F* demonstrate this result. Additional qualifications can of course eliminate these particular examples. Then there will be more examples with undesirable consequences, and more qualifications to eliminate them. So long as the qualifications must be expressed in the terms of standard logical dependence and independence, the project recapitulates the efforts of Searle and Woods.

According to (Conj-a) and (Disj-a), Wisdom and Armstrong can agree that disjunctive predicates do not stand for properties or universals and they can disagree about whether conjunctive predicates stand for properties or universals. Wisdom says they don't, Armstrong thinks that the arguments against disjunctive universals do not

apply to conjunctive universals. Everyone should agree that if a predicate *F* is equivalent to a disjunction of two different property predicates, *F* may be disjunctive or may not. That depends on how the disjuncts are related. Similar remarks apply to conjunctive predicates.

Some earlier examples of predicates, or similar predicates, appear in the following list:

A. **pale yellow** or **grayish yellow** (*WEAK YELLOW*),
B. **pale yellow** or **deep blue** *(BELLOW)*,
C. (greater than 5 and less than 7) or (greater than 4 and less than 6),
D. (greater than 5 and less than 7) and (greater than 4 and less than 6),
E. yellow or angry,
F. yellow and angry.

So far as one can discriminate just by means of predicate entailment or the presence or absence of logical relations, (A) and (B) are similar. Each is a disjunction of predicates that exclude each other.

Pale yellow and grayish yellow do not differ with respect to hue or saturation. They differ in brightness only to the extent necessary to have distinct locations in the Munsell color solid. Pale yellow and grayish yellow are determinate with respect the determinable weak yellow, and weak yellow in turn is determinate with respect to yellow.

Bellow is not a determinate color with respect to the determinable color. One wants to deny that it is a color at all, even though *BELLOW* is equivalent to a disjunction of color predicates.

Predicates (A)and (B) contrast sharply. **Pale yellow** and **grayish yellow** are as similar as they can be while still excluding each other. **Pale yellow** and **deep blue** are about as dissimilar as two colors can be. Direct ungrounded appeals to resemblance or being in the same dimension or having to do with one another will not solve our problem. A theoretically satisfactory treatment of the determinate-determinable relation should explain these resemblances rather than be explained by them. A new technical term *disjoint* marks the apparent difference between (A) and (B). **Pale yellow** and **deep blue** are disjoint predicate. **Pale yellow** and **grayish yellow** are not disjoint. The next section provides a definition of disjointness.

So far as one can discriminate just by means of predicate entailment or the presence or absence of logical relations, the components of (C) and (D) are logically unrelated. But (C) is not a conjunctive predicate, and (D) is not a disjunctive predicate. Something that satisfies both disjuncts of (C), ‘greater than 5 and less than 7’ and ‘greater than 4 or less than 6,’ can change continuously so as to satisfy the first but not the second, or can change continuously in the other direction along the same dimension so as to satisfy the second but not the first. ‘Greater than 5 and less than 7’ and ‘greater than 4 and less than 6’ obviously indicate overlapping intervals along the same dimension. (C) is a long-winded way of expressing ‘greater than 4 and less than 7’ which has no appearance of being disjunctive. In the same way, (D) is a long-winded way of expressing greater than 5 and less than 6’ which has no appearance of being conjunctive.

So far as one can discriminate just by means of predicate entailment or the presence or absence of logical relations, the components of (E) and (F), these components are related to each other in the same way as those

of (C) and (D). ‘Yellow’ and ‘angry’ are logically independent. A puzzle that the Korner-Searle Symposium poses is still unsolved. (E) is a disjunctive predicate. ‘Yellow’ is not a determinate of the determinable ‘yellow or angry’. (F) is a conjunctive predicate. ‘Yellow and angry’ is not a determinate of the determinable ‘yellow.’

Logically independent predicates can be determinates under the same determinable. ‘Yellow’ and ‘angry’ have an independence of a kind, indicated here by the new technical term *B-independence*, that has conditions in addition to those for logical independence. The next section specifies some conditions of *B-independence*.

7. Boundaries and Borderlines

‘*B-independence*’ stands for ‘boundary independence.’ The Munsell Color Solid is composed of non-overlapping regions that all share boundaries with other regions. The preliminary discussion in this section departs for a while from colors to consider a familiar, two-dimensional array of non-overlapping regions, the states in the United States. In case a map of the United States is not close at hand, the reader can look at Figure 7 , a simple map of the some of the states that figure in the following examples.

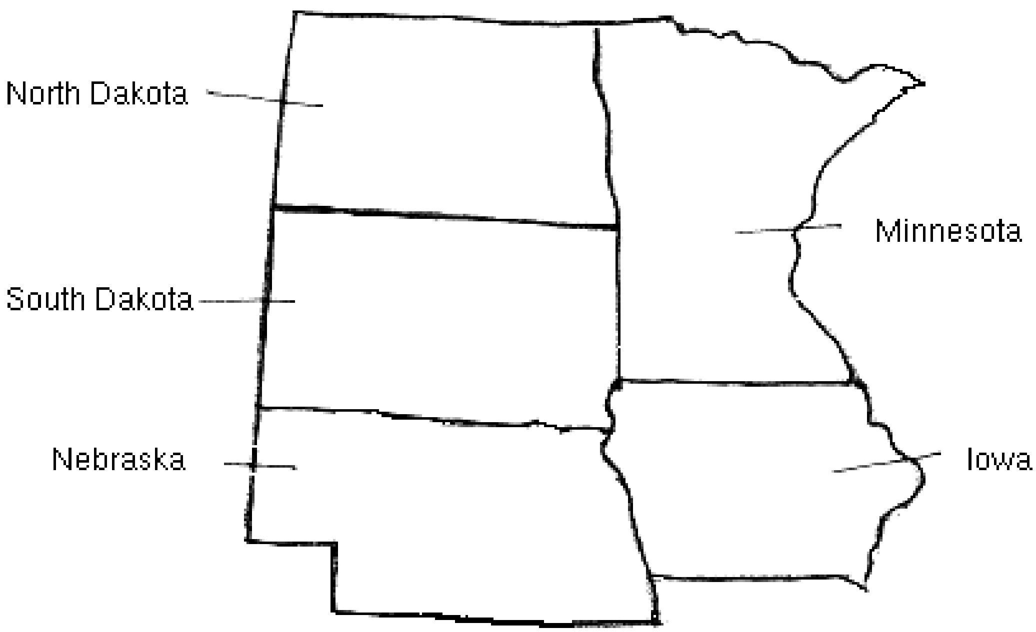

Figure 7

Some spatial analogies about the boundaries of states and other regions composed of the states will motivate the forthcoming discussion of *disjoint* and *B-independent* predicates. Here are two disjunctive definitions:

> x is in the Dakotas $=_{df}$ x is in North Dakota or x is in South Dakota.

> x is in the North States $=_{df}$ x is in North Dakota or x is in North Carolina.

In each case, the disjuncts exclude each other. North Dakota and South Dakota have no points in common. Neither do North Dakota and North Carolina. Predicate entailment fails to capture a topological difference between the Dakotas and the North States. The Dakotas are a coherent, continuous region. The North States

are a discontinuous region. Something can be both on the boundary of North Dakota and on the boundary of South Dakota. Nothing can be both on the boundary of North Dakota and on the boundary of North Carolina, for their boundaries are many miles apart. North Dakota and North Carolina are disjoint. North Dakota and South Dakota are not disjoint.

There is a close analogy here with some the color examples in the last section. Weak yellow is a coherent, continuous region in the quality space of color. Bellow is a discontinuous region. Something can be both on the boundary of pale yellow and on the boundary of grayish yellow. Nothing can be both on the boundary of pale yellow and deep blue. This is a topological difference that predicate entailment does not represent.

Here are two more disjunctive geographical definitions. In the first definition, the disjuncts exclude each other:

> *x* is in Dabraksa $=_{df}$ *x* is in South Dakota or *x* is in Nebraska.

In the second definition, the disjuncts overlap; they are logically independent; neither includes the other; they do not jointly exhaust the total space:

> *x* is in Longkota $=_{df}$ *x* is in the Dakotas or *x* is in Dabraska.

Longkota is a coherent, continuous region. There is nothing inherently disjunctive about it. Boundary relations again indicate topological relations between the Dakotas and Dabraska that logical entailment and non-entailment do not capture. Consider something *A* on the boundary of South Dakota and Minnesota and Iowa. It is on the boundary of the Dakotas and on the boundary of Debraska and on the boundary of Longkota. But it is not on the boundary of the following two regions:

> *x* is in the Dakotas but *x* is not in Debraska (that is, *x* is in North Dakota)

> *x* is in Debraska but *x* is not in the Dakotas (that is, *x* is in Nebraska).

A is not close to any boundary of North Dakota or Nebraska.

One of our main puzzle predicates, 'yellow or angry,' presents a topological contrast. Anything *A* on the boundary of 'yellow' and on the boundary of 'angry' is also on the boundary of the following four predicates:

> 'yellow and angry'
> 'yellow but not angry'
> 'angry but not yellow'
> 'neither angry nor yellow'

This reflects the fact that being yellow and being angry are conceptually independent besides being logically independent. Slight changes in *a* that would move it from the boundary of 'yellow' to being definitely yellow or definitely not yellow are independent of slight changes in *a* that would move it from the boundary of 'angry' to being definitely angry or definitely not angry.

It is possible to define a color predicate analogous to Longkota. This definition uses two earlier definitions that are repeated here:

> *ROBUST YELLOW*: **strong yellow** or **moderate yellow** or **grayish yellow**.
>
> *WEAK YELLOW*: **pale yellow** or **grayish yellow**
>
> *SWELL YELLOW*: *WEAK YELLOW* or *ROBUST YELLOW*.

The disjuncts of this last definition are logically independent. Nevertheless, *SWELL YELLOW* corresponds to a coherent continuous region in color space. Weak yellow and robust yellow have a topological relation that yellowness and anger do not have. There are locations in the Munsell Color Solid (for example, on the borderline of **grayish yellow** and on the borderline of **light olive brown**), where something *x* at this location is on the boundary of weak yellow and on the boundary of robust yellow and on the boundary of swell yellow but is not on the boundary of the following two regions:

> Weak yellow but not robust yellow.
> Robust yellow but not weak yellow.

Although the predicates *WEAK YELLOW* and *ROBUST YELLOW* are logically independent, relations between the boundaries of their regions indicate a significant, objective connection.

Although **pale yellow** is a highly determinate color predicate relative to ‘yellow’, it is far from being maximally determinate. A sentence from Kelly and Judd, quoted above in Section 4, is repeated here:

> There are many pairs of easily distinguishable colors which receive in this system the same designation, while there are also many pairs that can scarcely be distinguished which receive different designations(Kelly and Judd, 1976. p. 4).

Despite its relative specificity, **pale yellow** applies to samples that are visibly different with respect to color. The same goes for **grayish yellow**. So something can change gradually from pale yellow to grayish yellow. Is there some point along the way that is the precise boundary between these two color regions? This is a specific form of a question that divides philosophers who develop theories of vagueness. Without needing to adopt some view about the basic nature of borderline cases, one can admit the possibility of borderline cases between pale yellow and grayish yellow. It is possible that something can be on the borderline of each region. Something is a borderline case of pale yellow if it is neither definitely pale yellow nor definitely not pale yellow.

Körner also uses a logic of inexact concepts to treat ‘yellow or angry.’ One of Searle's complaints about Körner is that "His definition excludes any exact concept as a possible candidate for a determinate" (Searle, 1959, p. 156). Does this objection apply to the suggestions in this section? The next section returns to the question whether there are perfectly exact concepts. Borderline cases are used in this section to locate boundaries. Suppose that ‘more than five feet tall but less than six feet tall’ is perfectly exact. Anything just slightly taller than five feet or just slightly shorter than six feet is on the boundary. For the purposes of

exploring relations to other predicates, we can replace an exact predicate with one that it slightly inexact. For example, amend the definition of the allegedly exact predicate by adding ‘so far as one can tell by using a wall, a pencil, a carpenter’s level, and a yardstick.’ The definitions as amended definitely apply to some things, definitely do not apply to others, and also have some borderline cases left over. (Following a harmless practice, this article refers both to borderline cases of predicates and to borderline cases of properties or regions.)

This project treats borderlines and boundaries as interchangeable. The following is an attempt to generalize and formalize the suggestions made above:

> The ‘**B**’ operator is used to talk about boundaries and borderline cases. ‘**B***Fx*’ means ‘*x* is a borderline case of *F*.’

The definition of *disjoint predicates* promised at the end of the section follows:

> *Fx* and *Gx* are disjoint predicates if and only if *Fx* and *Gx* are exclusive predicates and For any *x*, if **B***Fx*, then not-**B***Gx*.

Disjoint predicates do not, or in a modal version, cannot, share borderline cases. A predicate is *exclusively disjunctive* if and only it is equivalent to a disjunction of disjoint predicates.

A specification of a condition of **B**-*independence* was also promised at the end of Section 5. Let us say that two predicates *Fx* and *Gx* intersect if and only if there is something *x* such that:

> **B**(*F* & *G*)*x* & **B**(*F* & not-*G*)*x* & **B**(not-*F* & *G*)*x* & (not-*F* & not-*G*)*x*.

The boundaries of **B**-*independent* predicates not only intersect; they intersect wherever they have a point in common. *Fx* and *Gx* are **B**-*independent* only if:

> For any *x*, if **B***Fx* and **B***Gx*, then **B**(*F* & *G*)*x* & **B**(*F* & not-*G*)*x* & **B**(not-*F* & *G*)) & **B**(not-*F* & not-*G*)*x*.

A predicate is *inclusively disjunctive* only if it is equivalent to a disjunction of **B**-*independent* predicates. A predicate is *conjunctive* only if it is equivalent to a conjunction of **B**-*independent* predicates. ‘Yellow or angry’ is inclusively disjunctive. *WEAK YELLOW* or *ROBUST YELLOW* is not inclusively disjunctive. ‘Yellow and angry’ is conjunctive. ‘*WEAK YELLOW* and *ROBUST YELLOW*’ is not conjunctive.

This approach appears to solve the puzzle that Körner formulated and that Searle and others attempted to solve without success. Conjunctive predicates do not correspond to determinates. Disjunctive predicates do not correspond to determinables.

The discussion above provides only a necessary condition of B-independence. Attempting to deal with Nelson Goodman's puzzle about ‘grue’ and other perverse artificial predicates requires reference to more complicated relations between boundary conditions. These further conditions which are represented as both necessary and

sufficient for **B**-*independence* are not spelled out here. They appear, in successive versions, in three articles by Sanford 1970, 1981 (in which the later parts are nearly incomprehensible because of over-compression and lack of diagrams), and 1994 (which has some diagrams). All three articles attempt to clarify the determinate-determinable relation by explaining the nature of disjunctive and conjunctive predicates.

8. Absolute Determinacy

“The practical impossibility of literally determinate characterization must be contrasted with the universally adopted postulate that the characters of things which we can only characterise more or less indeterminately, are, in actual fact, absolutely determinate.” This is the final sentence of W. E. Johnson's chapter “The Determinable.” Johnson is not the only philosopher who holds that things are absolutely determinate. One of D. M. Armstrong's six numbered refutations of phenomenalism in Armstrong (1961) maintains that “physical objects, which are determinate, cannot be constructions out of indeterminate sense-impressions” (p. 58).

> A physical object is determinate in all respects, it has a perfectly precise colour, temperature, size, etc. It makes no sense to say that a physical object is light-blue in colour, but is no definite shade of light blue. (p. 59)

Understanding what it is for color, temperature, size, etc., predicates to be perfectly precise helps in understanding what it is for color, temperature, size, etc., properties to be perfectly precise. A precise predicate is not vague; it is exact rather than inexact; it has no borderline cases. Precision contrasts with vagueness.

Specificity, on the other hand, contrasts with generality. **Light blue** is more specific than ‘blue’ which is more specific than ‘colored.’ The more specific a predicate, the narrower the range it covers. Is **light blue** more specific than ‘smooth’? The absence of an inclusion relation in either direction makes it difficult to answer this question. Attempts actually to compare the numerical results after counting all the light blue things in the world and all the smooth things can lead only to frustration and failure. This entry does not address the problem of comparing degrees of specificity of determinates under different determinables.

Specificity and exactness are independent in several ways. There can be predicates *F* and *G* such that:

> *F* and *G* are not identical and are both unspecific and inexact. For example: *F*: about the size of a cat, *G*: about the size of a dog.
>
> *F* is more specific and more exact than *G*. Example: *F*: **pale yellow** and *G*: yellow (in the ordinary rather inclusive sense).
>
> *F* is more specific than *G*, and *G* is more exact than *F*. Example: *F*: about the size of a cat. *G*: has a volume not less than 50.3 cubic inches and not more than 2000.8 cubic inches. Anything *F* is *G* and not everything *G* is *F*, so *F* is more specific than *G*. But *G* is more exact. It requires, at the boundaries, determination to the nearest tenth of a cubic inch.
>
> *F* and *G* are both specific and exact. Examples: *F*: **pale yellow**, *G*: **deep blue**. Neither of these

> color predicates is absolutely precise, but each is quite precise compared to ordinary color terms. The Munsell Color Solid is constructed with the intention that each of the 267 regions has approximately the same degree of specificity.

Although specificity and precision are independent in these ways, they are also significantly connected with respect to absolute determinacy. Any absolutely specific predicate is also absolutely precise. Suppose, for example, that ‘Armstrong blue’ is a predicate for an absolutely specific shade of blue. Two things that are Armstrong blue do not differ at all with respect to hue or brightness or saturation. Given a predicate ‘*F*’ and two objects *a* and *b* such that *a* is a borderline case of ‘*F*’ and *b* is a definite positive case of ‘*F*’, *a* and *b* differ along some relevant dimension. But anything that differs along any relevant dimension from something that is definitely *F*, when ‘*F*’ is an absolutely specific predicate, is not *F*. Absolutely specific predicates cannot have borderline cases.

No predicate that can have borderline cases is absolutely specific. So if there are no absolutely precise or exact predicates, neither are there absolutely specific predicates. Johnson presumably would not question this conclusion since he says that literally determinate characterization is practically impossible. He and Armstrong claim things in the world are absolutely determinate, not the predicates we do or could use to apply to things in the world.

If things in the world are absolutely determinate, this presumably does not require that any absolute determination persists through the passage of time or space. If a cumulus cloud changes continuously in shape and size, this does not by itself preclude its having, at any one time, an absolutely determinate shape and size. The impression that clouds do not have exact boundaries, however, is probably not based entirely on their changeability.

Objects with absolutely determinate sizes have absolutely determinate boundaries. If a thing has an absolutely determinate length along some axis at a given time, then there is exactly one real number *n* such that its length in (say) meters is *n*. Things that we come across in ordinary life such as plants, animals, buildings, furniture, electronic equipment, clothing, and kitchenware do not have exact boundaries, nor do larger items such as mountains, lakes, continents, and stars.

The view that things in the world are absolutely determinate is implausible if it requires clouds, brains, and dinner plates to be absolutely determinate. But this requirement can be put aside. If the microstructure of the world is absolutely determinate, that is absolute determinacy enough. If all the atoms within you and in your vicinity have absolutely determinate properties, then the indeterminate mass and shape and volume of you, your brain, and your teeth somehow supervene on the determinate microstructure. Here is a well-known passage from David Lewis:

> The reason it's vague where the outback begins is not that there's this thing, the outback, with imprecise borders; rather there are many things, with different borders, and nobody has been fool enough to try to enforce a choice of one of them as the official referent of the word ‘outback.’ (Lewis, 1986, p. 212)

The view that there are many things with precise borders does not by itself refute the view that there are things

with imprecise borders. Here is a kind of parody of the passage just quoted. It ends with the same point but begins with a contrary contention:

> The outback is a big thing, and it is vague where it begins. The reason it has imprecise borders is that there are many things, with different precise borders, and nobody has been fool enough to enforce a choice of one of them as the official reference of the word ‘outback’.

For the outback (a cloud, your brain), there are many more-or-less precise aggregates of particles such that each is about as good a candidate as there is to be identified with the outback (a cloud, your brain). This entry does not address the problem of the many, how to understand the relation between a single macro-object and many overlapping aggregates of micro-objects that more or less coincide with it.

However one resolves the problem of the many, the question of absolute determinacy becomes the question of absolute determinacy of the physical basis, the microstructure. After quoting the passage from Lewis above, Roberto Casati and Achille Varzi write:

> There are plenty of objects out there—plenty of slightly distinct and yet precisely determinate aggregates of land molecules. And when we say ‘Mount Everest’ or ‘the outback’, each one of a large variety of such aggregates—each with its own perfectly crisp mereotopological structure—has an equal claim to being a referent of that term. (Casati and Varzi, 1999, p. 95)

And what evidence is there for this precisely determinate perfect crispness? Logic and metaphysics cannot answer this question from its own resources. Science textbooks represent particles and atoms as clouds. Textbook writers fifty years ago knew that the picture of perfect little spheres, the electrons, in elliptical orbits around a nucleus was misleading. Now the picture is simply obsolete.

An attempt to measure the precise dimensions of a polished copper cube might begin using an ordinary school supply ruler, then using a machinist's steel rule, then using a micrometer, then, starting with a low power optical microscope, using a series of increasingly powerful microscopes. At the microscopic level one can discriminate increments of length too small for a mechanical micrometer to detect. This does not produce a more precise determination of the length of the cube if nothing at this level coincides with the boundary of the cube. So the search for the exact measurements of the cube is abandoned and replaced by a hope to find absolute determinacy somewhere at the foundations, the fundamental basis, or the limit. There is a (weak) kind of non-deductive argument here.

> Given a greatest degree of precision determined by the best instruments, sooner or later a more advanced technology produces instruments that are still more precise. This process of making measurement increasingly precise never ends; it asymptotically approaches absolute precision at dimensionless points of matter or spacetime or something.

This vision of absolute determinacy at the limit is apparently attractive. It appears to be internally consistent. It also appears, however, to be inconsistent with physics.

Middle-sized objects do not have perfectly precise boundaries because there are microscopic objects that are

neither definitely included nor definitely excluded from the object. Some larger microscopic objects lack perfectly precise boundaries for the same reason. There is no reason to believe that this process continues infinitely downward. Electron diameters are imprecise, but not because there are swarms of micro-electron-dust, each particle of which is also a swarm of something even smaller. Nor does the process stop with some basic items that really are absolutely determinate.

Instruments can measure the velocity of a tennis ball. They do not, of course, measure velocity with absolutely determinacy. They do not discriminate, say, 114.0 from 114.1 miles per hour. Given some understanding of margins of error, it is meaningful for one to say that a tennis ball was going 114 miles per hour at some temporal instant *t*. The notions of a limit and of convergence provide this meaning. They provide no support for believing in the possibility of a momentary tennis ball that exists neither before instant *t* nor after instant *t* but does exist precisely at instant *t* and travels 114 miles per hour during its instantaneous existence. If it is possible for something to have a property for an instant, it does not follow that an instantaneous thing can have that property.

The same goes for spatial points. If it is possible for something to have a property at a point, it does not follow that it is possible that something punctiform should have this property. When a region is pale yellow, we can say that any point in the region is pale yellow. But no point by itself can be pale yellow.

Johnson said that it is a "universally adopted postulate that the characters of things which we can only characterise more or less indeterminately, are, in actual fact, absolutely determinate." In saying it is a postulate, Johnson does not mean we merely assume it in order to deduce its consequences. He means rather that it is both obviously true and cannot be inferred from truths that are even more obvious. But the so-called postulate seems not to be true.

Relative Identity

Identity is often said to be a relation each thing bears to itself and to no other thing (e.g., Zalabardo, 2000). This characterization is clearly circular ("no *other* thing") and paradoxical too, unless the notion of "each thing" is qualified. More satisfactory (though partial) characterizations are available and the idea that such a relation of absolute identity exists is commonplace. Some, however, deny that a relation of absolute identity exists. Identity, they say, is relative: It is possible for objects *x* and *y* to be the same *F* and yet *not* the same *G*, (where *F* and *G* are predicates representing kinds of things (apples, ships, passengers) rather than merely properties of things (colors, shapes)). In such a case 'same' cannot mean absolute identity. For example, the same person might be two different passengers, since one person may be counted twice as a passenger. If to say that *x* and *y* are the same person is to say that *x* and *y* are persons and are (absolutely) identical, and to say that *x* and *y* are different passengers is to say that *x* and *y* are passengers and are (absolutely) distinct, we have a contradiction. Others maintain that while there are such cases of "relative identity," there is also such a thing as absolute identity. According to this view, identity comes in two forms: trivial or absolute and nontrivial or relative (Gupta, 1980). These maverick views present a serious challenge to the received, absolutist doctrine of identity. In the first place, cases such as the passenger/person case are more difficult to dismiss than might be supposed (but see below, §3). Secondly, the standard view of identity is troubled by many persistent puzzles and problems, some of recent and some of ancient origin. The relative identity alternative sheds considerable light on these problems even if it does not promise a resolution of them all.

A word about notation. In what follows, lower case italic letters '*x*', '*y*', etc., are used informally either as variables (bound or free) or as (place-holders for) individual constants. The context should make clear which usage is in play. Occasionally, for emphasis or in deference to logical tradition, other expressions for individual constants are employed. Also, the use/mention distinction is not strictly observed; but again the context should resolve any ambiguity.

1. The Standard Account of Identity

[Note: The following material is somewhat technical. The reader may wish to casually review it now and return to it as needed, especially in connection with §5. The propositions **Ref**, **LL**, **Ref′**, **LL′**, **NI**, and **ND** are identified in the present section and are referred to as such in the rest of the entry.]

Identity may be formalized in the language *L* of classical first-order logic (FOL) by selecting a two place predicate of *L*, rewriting it as '=', and adopting the universal closures of the following two postulates:

(**Ref**): $x = x$
(**LL**): $x = y \rightarrow [\wp(x) \rightarrow \wp(y)]$,

where the formula $\wp(x)$ is like the formula $\wp(y)$ except for having occurrences of x at some or all of the places $\wp(y)$ has occurrences of y (see Enderton, 2000, for a precise definition). Ref is the principle of the *reflexivity of identity* and LL (*Leibniz' Law*) is the principle of the *indiscernibility of identicals*. It says in effect that identical objects cannot differ in any respect. The other characteristic properties of identity, *symmetry* ($x = y \rightarrow y = x$), and *transitivity* ($x = y$ & $y = z \rightarrow x = z$), may be deduced from Ref and LL. Any relation that is reflexive, transitive, and symmetric is called an 'equivalence relation'. Thus, identity is an equivalence relation satisfying LL. But not all equivalence relations satisfy LL. For example, the relation *x and y are the same size* is an equivalence relation that does not satisfy LL (with respect to a rich language such as English).

Let *E* be an equivalence relation defined on a set *A*. For *x* in *A*, [*x*] is the set of all *y* in *A* such that *E*(*x*, *y*); this is *the equivalence class of x determined by E*. The equivalence relation *E* divides the set *A* into mutually exclusive equivalence classes whose union is *A*. The family of such equivalence classes is called 'the partition of *A* induced by *E*'.

Now let *A* be a set and define the relation *I*(*A*,*x*,*y*) as follows: For *x* and *y* in *A*, *I*(*A*,*x*,*y*) if and only if for each subset *X* of *A*, either *x* and *y* are both elements of *X* or neither is an element of *X*. This definition is equivalent to the more usual one identifying the identity relation on a set *A* with the set of ordered pairs of the form <*x*,*x*> for *x* in *A*. The present definition proves more helpful in what follows.

Suppose for the moment that we do not assign any special interpretation to the identity symbol. We treat it like any other two place predicate. Let *M* be a structure for *L* and assume that Ref and LL are true in *M*. Call the relation defined in *M* by the conjunction of Ref and LL 'indiscernibility' (see Enderton, 2000, for the definition of definability in a structure). There are three important points to note about the relationship between indiscernibility, and the relation *I*(*A*,*x*,*y*). First, indiscernibility need not be the relation *I*(*A*,*x*,*y*)

(where *A* is the domain of the structure). It might be an equivalence relation *E* having the property that for some elements *u*,*v*, of the domain, *E*(*u*,*v*) holds, although *I*(*A*,*u*,*v*) fails. Secondly, there is no way to "correct for" this possibility. There is no sentence or set of sentences that could be added to the list beginning with Ref and LL that would guarantee that indiscernibility coincides with *I*(*A*,*x*,*y*). This fact is usually expressed by saying that identity is not a first-order or "elementary" relation. (For a proof, see Hodges, 1983.) However, in a language such as set theory (as usually interpreted) or second-order logic, in which there is a quantifier 'all *X*' permitting quantification over all subsets of a given set, *I*(*A*,*x*,*y*) is definable.

Third, given any structure *M* for *L* in which Ref and LL are true, there is a corresponding structure *QM*, the 'quotient structure' determined by *M*, in which indiscernibility *does* coincide with *I(A*,*x*,*y*). *QM* is obtained in roughly the following way: Let the elements of *QM* be the equivalence classes [*x*], for elements *x* of *M* determined by indiscernibility in *M*. If *F* is a one-place predicate true in *M* of some object *x* in *M*, then define *F* to be true of [*x*] in *QM*, and similarly for many-place predicates and constants. It can then be shown that any sentence true in *M* is true in *QM*, and vice versa. The existence of quotient structures makes it possible to treat the identity symbol as a logical constant interpreted in terms of *I(A*,*x*,*y*). There is in fact in general no other way to *guarantee* that Ref and LL will hold in every structure. (As Quine (1970) points out, however, a *finite* language will always contain a predicate satisfying Ref and LL in any structure; cf. Hodges, 1983.) The alternative, however, is to view FOL with Ref and LL ($FOL^=$) as a proper theory in whose models (structures in which Ref and LL hold) there will be an equivalence relation *E* such that if *E*(*x*,*y*) holds, then *x* and *y* will be indiscernible with respect to the *defined* subsets of the domain. But we cannot in general assume that every subset of the domain is definable. If the domain is infinite, *L* runs out of defining formulas long before the domain runs out of subsets. Nonetheless, a strong metatheorem asserts that any set of formulas that has a model, has a countable (finite or denumerable) model. This means that the difference between indiscernibility and *I(A*,*x*,*y*) is minimized at least to the extent that, for a sufficiently rich language such as *L*, the valid formulas concerning indiscernibility (i.e., the formulas true in every model of what is termed below 'the pure *L*-theory with identity') coincide with the valid formulas concerning *I*(*A*,*x*,*y*). (See Epstein, 2001 for a sketch of a proof of this fact.) This is not to say, however, that there isn't a significant difference between identity *qua* indiscernibility and identity *qua* *I*(*A*,*x*,*y*) (see below). Both points of view -- that $FOL^=$ is a proper theory and that it is a logic -- may be found in th literature (Quine, 1970). The latter is the more usual view and it will count here as part of the standard account of identity.

Assume that L' is some fragment of *L* containing a subset of the predicate symbols of *L* and the identity symbol. Let *M* be a structure for L' and suppose that some identity statement $a = b$ (where *a* and *b* are individual constants) is true in *M*, and that Ref and LL are true in *M*. Now expand *M* to a structure M' for a richer language -- perhaps *L* itself. That is, assume we add some predicates to L' and interpret them as usual in *M* to obtain an expansion M' of *M*. Assume that Ref and LL are true in M' and that the interpretation of the terms *a* and *b* remains the same. Is $a = b$ true in M'? That depends. If the identity symbol is treated as a logical constant, the answer is "yes." But if it is treated as a non-logical symbol, then it can happen that $a = b$ is false in M'. The indiscernibility relation defined by the identity symbol in *M* may differ from the one it defines in M'; and in particular, the latter may be more "fine-grained" than the former. In this sense, if identity is treated as a logical constant, identity is *not* "language relative;"

whereas if identity is treated as a non-logical notion, it *is* language relative. For this reason we can say that, treated as a logical constant, identity is 'unrestricted'. For example, let L' be a fragment of L containing only the identity symbol and a single one-place predicate symbol; and suppose that the identity symbol is treated as non-logical. The formula

$$\forall x \forall y \forall z(x = y \lor x = z \lor y = z)$$

is then true in any structure for L' in which Ref and LL are true. The reason is that the unique one-place predicate of L' divides the domain of a structure into those objects it satisfies and those it does not. Hence, at least two of any group of three objects will be indiscernible. On the other hand, if the identity symbol is interpreted as $I(A,x,y)$, this formula is false in any structure for L' with three or more elements.

If we do wish to view identity as a non-logical notion, then the phenomenon of language relativity suggests that it is best not to formalize identity using a single identity predicate '='. Instead, we have the following picture: We begin with a language L and define an *L-theory with identity* to be a theory whose logical axioms are those of FOL and which is such that L contains a two-place predicate E_L satisfying the non-logical axiom Ref' and the non-logical axiom schema LL$'$:

(**Ref$'$**): $E_L(x,x)$

(**LL$'$**): $E_L(x,y) \rightarrow (\varphi(x) \rightarrow \varphi(y))$.

The *pure L*-theory with identity is the L-theory whose sole non-logical axiom is Ref' and whose sole non-logical axiom schema is LL$'$.

Now the phenomenon of language relativity can be described more accurately as follows. Let L_1 be a sublanguage of L_2 and assume that T_1 and T_2 are, respectively, the pure L_1-theory with identity and the pure L_2-theory with identity. Let M_1 and M_2 be models of T_1 and T_2, respectively, having the same domain. Assume that a and b are individual constants having the same interpretation in M_1 and M_2. Let E_1 and E_2 be the identity symbols of L_1 and L_2. It can happen that $E_1(a,b)$ is true in M_1 but $E_2(a,b)$ is false in M_2. We can then say, with Geach (1967; see §4) and others, that the self-same objects indiscernible according to one theory may be discernible according to another.

There are two further philosophically significant features of the standard account of identity. First, identity is a *necessary* relation: If a and b are rigid terms (terms whose reference does not vary with respect to parameters such as time or possible world) then

(**NI**): If $a = b$ is true, then it is necessarily true.

Assuming certain modal principles, the necessity of distinctness (ND) follows from NI.

(**ND**): If $a \neq b$ is true, then it is necessarily true.

Note that the necessary truth of *a* = *b* does not imply the necessary existence of objects *a* or *b*. We may assume that what a rigid term *a* denotes at a possible world (or moment of time) *w* need not exist in *w*. Secondly, we do not ordinarily say things of the form "*x* is the same as *y*". Instead, we say "*x* and *y* are the same person" or "*x* and *y* are the same book". The standard view is that the identity component of such statements is just ‘*x* is the same as *y*’. For example, according to the standard view, ‘*x* and *y* are the same person’ reduces to ‘*x* and *y* are persons and *x* is the same as *y*’, where the second conjunct may be formalized as in $FOL^=$.

2. Paradoxes of Identity

The concept of identity, simple and settled though it may seem (as characterized by the standard account), gives rise to a great deal of philosophical perplexity. A few (by no means all) of the salient problems are outlined below. These are presented in the form of paradoxes -- arguments from apparently undeniable premises to obviously unacceptable conclusions. The aim here is to make clear just what options are available to one who would stick close to the standard account. Often (but not always) little or no defense or critique of any particular option is offered. In the next section, we shall see what the relative identity alternative offers by comparison.

2.1 The Paradox of Change

The most fundamental puzzle about identity is the problem of change. Suppose we have two photographs of a dog, Oscar. In one, *A*, Oscar is a puppy, in the other, *B*, he is old and gray muzzled. Yet we hold that he is the same dog, in, it appears, direct violation of LL. More explicitly, *B* is a photograph of an old dog with a gray muzzle; *A* is a photograph of a young dog without a gray muzzle. *A* and *B* are photographs of the same dog. But according to LL, if the dog in *B* has a property (e.g., having a gray muzzle) that the dog in *A* lacks, then *A* and *B* are *not* photographs of the same dog. Contradiction.

Various solutions have been proposed. The most popular are the following two: (1) Simple properties such as having or lacking a gray muzzle are actually relations to times. Oscar has the property of lacking a gray muzzle *at time t* and the property of having a gray muzzle at (a later) t'; but there is no incompatibility, since being thus and so related to time *t* and not being thus and so related to time t' are compatible conditions, and hence change involves no violation of LL. (2) Oscar is an object that is extended in time as well as space. The puppy Oscar and old gray muzzled Oscar are distinct temporal parts or stages of the whole temporally extended Oscar. The photograph of Oscar as a puppy is therefore not a photograph of Oscar at all. There cannot be still photographs of Oscar.

These proposals may seem plausible, and indeed most philosophers subscribe to one or other of them. The most common objections -- that on the temporal parts account, objects are not "wholly present" at any given time, and that on the relations-to-times account, seemingly simply properties of objects, such as

Oscar having a gray muzzle, are complicated relations -- do little more than affirm what their targets deny. Yet the objections are an attempt to give voice to a strong intuition concerning our experience as creatures existing in time. Both (1) and (2) treat time and change from a "God's eye" point of view. (1) presupposes time laid out "all at once", so to speak, and similarly for (2). But we experience no such thing. Instead, while we are prepared to wait to see the whole of a baseball game we are watching, we are not prepared to wait to see the whole of painting we are viewing..

2.2 Chrysippus' Paradox

The following paradox -- a variation of the paradox of change -- raises some new questions. It is due to the Stoic philosopher Chrysippus (c.280 B.C.-c.206 B.C.) and has recently been resurrected by Michael Burke (Burke, 1994). Suppose that at some point t' in the future poor Oscar loses his tail. Consider the proper part of Oscar, as he is now (at t), consisting of the whole of Oscar minus his tail. Call this object ‘ Oscar-minus ‘. Chrysippus wished to know which of these objects -- Oscar or Oscar-minus -- survives at t'. According to the standard account of identity, Oscar and Oscar-minus are distinct at t. and hence, by ND, they are distinct at t'. (Intuitively, Oscar and Oscar-minus are distinct at t' since Oscar has a property at t' that Oscar-minus lacks, namely, the property of having had a tail at t. Notice that this argument involves a tacit appeal to ND -- or NI, depending on how you look at it). Hence, if both survive, we have a case of two distinct physical objects occupying exactly the same space at the same time. Assuming that is impossible, and assuming, as commonsense demands, that Oscar survives the loss of his tail, it follows that Oscar-minus does not survive. This conclusion is paradoxical because it appears that *nothing happens* to Oscar-minus in the interval between t and t' that would cause it to perish.

One extreme option is to deny that there are such things as Oscar-minus. Undetached proper parts of objects don't exist (van Inwagen, 1981). Another is to claim that the parts of an object are essential to it (Chisholm, 1973). A third, less extreme, option is to insist that objects of *different* kinds, e.g., a clay statue and the piece of clay it is composed of, *can* occupy the same space at the same time, but objects of the same kind, e.g., two statues, cannot (Wiggins, 1968; for refinements, see Oderberg, 1996). A fourth option is to claim that Oscar and Oscar-minus are two distinct, temporally extended objects -- a dog part, Oscar-minus, and a dog, Oscar -- that overlap at t'. Temporal parts of distinct objects can occupy the same space at the same time.

2.3 The Paradox of 101 Dalmatians

(This paradox is also known as the paradox of 1001 cats; Geach, 1980, Lewis, 1993): Focus on Oscar and Oscar-minus at t -- before Oscar loses his tail. Is Oscar-minus a dog? When Oscar loses his tail the resulting creature is certainly a dog. Why then should we deny that Oscar-minus is a dog? We saw above that one possible response to Chrysippus' paradox was to claim that Oscar-minus does not exist at t'. But even if we adopt this view, how does it follow that Oscar-minus, existing as it does at t, is not a dog? Yet if Oscar-minus is a dog, then, given the standard account of identity, there are two dogs where we would normally count only one. In fact, for each of Oscar's hairs, of which there are at least 101, there is a proper part of Oscar -- Oscar minus a hair -- which is just as much a dog as Oscar-minus. There are then

at least 101 dogs (and in fact many more) where we would count only one. Some claim that things such as dogs are "maximal." No proper part of a dog is a dog (Burke, 1993). One might conclude as much simply to avoid multiplying the number of dogs populating the space reserved for Oscar alone. But the maximality principle may seem to be independently justified as well. When Oscar barks, do all these different dogs bark in unison? If a thing is a dog, shouldn't it be capable of independent action? Yet Oscar-minus cannot act independently of Oscar. Nevertheless, David Lewis (1993) has suggested a reason for counting Oscar-minus and all the 101 dog parts that differ (in various different ways) from one another and Oscar by a hair, as dogs, and in fact as Dalmatians (Oscar is a Dalmatian). Lewis invokes Unger's (1980) "problem of the many." Oscar sheds continuously but gradually. His hairs loosen and then dislodge, some such remaining still in place. Hence, within Oscar's compass at any given time there are congeries of Dalmatian parts sooner or later to become definitely Dalmatians; some in a day, some in a second, or a split second. It seems arbitrary to proclaim a Dalmatian part that is a split second away from becoming definitely a Dalmatian, a Dalmatian, while denying that one a day away is a Dalmatian. As Lewis puts it, we must either deny that the "many" are Dalmatians, or we must deny that the Dalmatians are many. Lewis endorses proposals of both types but seems to favor one of the latter type according to which the Dalmatians are not many but rather "almost one" In any case, the standard account of identity seems unable on its own to handle the paradox of 101 Dalmatians. It requires that we either deny that Oscar minus a hair is a dog -- and a Dalmatian -- or else that we must affirm that there is a multiplicity of Dalmatians, all but one of which is incapable of independent action and all of which bark in unison no more loudly than Oscar barks alone.

2.4 The Paradox of Constitution

Suppose that on day 1 Jones purchases a piece of clay c and fashions it into a statue s_1. On day 2, Jones destroys s_1, but not c, by squeezing s_1 into a ball and fashions a new statue s_2 out of c. On day 3, Jones removes a part of s_2, discards it, and replaces it using a new piece of clay, thereby destroying c and replacing it by a new piece of clay, c'. Presumably, s_2 survives this change. Now what is the relationship between the pieces of clay and the statues they "constitute?" A natural answer is: identity. On day 1, c is identical to s_1 and on day 2, c is identical to s_2. On day 3, s_2 is identical to c'. But this conclusion directly contradicts NI. If, on day 1, c is (identical to) s_1, then it follows, given NI, that on day 2, s_1 is s_2 (since c is identical to s_2 on day 2) and hence that s_1 exists on day 2, which it does not. By a similar argument, on day 3, c is c' (since s_2 is identical to both) and so c exists on day 3, which it does not. We might conclude, then, that either constitution is not identity or that NI is false. Neither conclusion is wholly welcome. Once we adopt the standard account less NI, the latter principle follows directly from the assumption that individual variables and constants in quantified modal logic are to be handled exactly as they are in first-order logic. And if constitution is not identity, and yet statues, as well as pieces of clay, are physical objects (and what else would they be?), then we are again forced to affirm that distinct physical objects may occupy (exactly) the same space at the same time. The statue s_1 and the piece of clay c occupy the same space on day 1. Even if this is deemed possible (Wiggins, 1980), it is unparsimonious. The standard account is thus *prima facie* incompatible with the natural idea that constitution is identity.

Philosophers have not argued by direct appeal to NI or ND. Typically, (e.g., Gibbard, 1975, Noonan, 1993, Johnston, 1992), arguments that *c* and s_1 are not identical run as follows: *c* exists prior to the existence of s_1 and hence the two are not identical. Again, s_1 possesses the property of being such that it will be destroyed by being squeezed into a ball, but *c* does not possess this property (*c* will be squeezed into a ball but it will not thereby be destroyed). So again the two are not identical. Further, whatever the future in fact brings, *c might* have been squeezed into a ball and not destroyed. Since that is not true of s_1, the two are not identical. On a careful analysis, however, each of these arguments can be seen to rely on NI or ND, *provided one adopts the standard account of modal/temporal predicates.* This last proviso suggests an interesting way out for one who adheres to the standard account of identity but who also holds that constitution is identity (see below).

Some philosophers find it important or at least expedient to frame the issue in terms of the case of a statue *s* and piece of clay *c* that coincide throughout their entire existence. We bring both *c* and *s* into existence by joining two other pieces of clay together, or we do something else that guarantees total coincidence. It seems that total coincidence is supposed to lend plausibility to the claim that, in such a case at least, constitution is identity (and hence NI is false -- Gibbard, 1975). It may do so, psychologically, but not logically. The same sorts of arguments against the thesis that constitution is identity apply in such a case. For example, *s* may be admired for its aesthetic traits, even long after it ceases to exist, but this need not be true of *c*. And *s* has the property, which *c* lacks, of being destroyed if squeezed into a ball. Those who defend the thesis that constitution is identity need to defend it in the general case of partial coincidence; and those who attack the thesis do so with arguments that work equal well against both total and partial coincidence. The assumption that *s* and *c* are totally coincident is therefore inessential.

The doctrine of temporal parts offers only limited help. The statement that *c* is identical to $s_1$on day 1 but identical to s_2 on day 2 can be construed to mean that *c* is a temporally extended object whose day 1 stage is identical to s_1 and whose day 2 stage is identical to s_2. Since the two stages are not identical, NI does not apply. Similarly, we can regard s_2 as a temporally extended object that overlaps *c* on day 2 and c' on day 3. But unless temporal parts theorists are prepared to defend a doctrine of modally extended objects -- objects extended through possible worlds analogous to objects extended in time, there remains a problem. s_2 *might* have been made of a different piece of clay, as is in fact the case on day 3. That is, it is logically possible for s_2 to fail to coincide with the day 2 stage of *c*. But it is not logically possible for the day 2 stage of *c* to fail to coincide with itself.

Lewis recognizes this difficulty and proposes to deal with it by appealing to his counterpart theory (Lewis, 1971, 1986, and 1993). Different concepts, e.g., *statue* and *piece of clay* are associated with different counterpart relations and hence with different criteria of trans-world identity. This has the effect of rendering modal predicates "Abelardian" (Noonan, 1991, 1993). The property determined by a modal predicate may be affected by the subject term of a sentence containing the predicate. The subject term denotes an object belonging to this or that kind or sort. But different kinds or sorts may determine different properties (or different counterpart relations). In particular, the properties determined by the predicate 'might not have coincided with c_2' (where c_2 names the day 2 stage of *c*) in the following

sentences,

(a) s_2 might not have coincided with c_2,

(b) c_2 might not have coincided with c_2,

are *different*, and hence (a) and (b) are compatible, even assuming that s_2 and c_2 are identical. (It should be emphasized that counterpart theory is not the only means of obtaining Abelardian predicates. See Noonan, 1991.)

The upshot seems to be that that the advocate of the standard account of identity must maintain either that constitution is not identity or that modal predicates are Abelardian. The latter option may be the fruitful one, since for one thing it seems to have applications that go beyond the issue of constitution.

2.5 The Ship of Theseus Paradox

(See Plutarch, *Life of Theseus*.) Imagine a wooden ship restored by replacing all its planks and beams (and other parts) by new ones. Plutarch reports that such a ship was "... a model for the philosophers with respect to the disputed arguments ... some of them saying it remained the same, some of them saying it did not remain the same" (cf. Rea, 1995). Hobbes added the catch that the old parts are reassembled to create another ship exactly like the original. Both the restored ship and the reassembled one appear to qualify equally to be the original. In the one case, the original is "remodeled", in the other, it is reassembled. Yet the two resulting ships are clearly not the same ship.

Some have proposed that in a case like this our ordinary "criteria of identity" fail us. The process of dismantling and reassembling usually preserves identity, as does the process of part replacement (otherwise no soldier could be issued just one rifle and body shops would function as manufacturers). But in this case the two processes produce conflicting results: We get two ships, one of which is the same ship as the original, by one set of criteria, and the other is the original ship by another set of criteria. There is a similar conflict of criteria in the case of personal identity: Brain duplication scenarios (Wiggins, 1967, Parfit, 1984) suggest that it is logically possible for one person to split into two competitors, each with equal claim to be the original person. We take it for granted that brain duplication will preserve the psychological properties normally relevant to reidentifying persons and we also take it for granted that the original brain continues to embody these properties even after it is duplicated. In this sense there is a conflict of criteria. Such a case of "fission" gives us two distinct embodiments of these properties.

Perhaps we should conclude that identity is not what matters. Instead, what matters is some *other* relation, but one that accounts as readily as identity for such facts as that the owner of the original ship would be entitled to both the restored version and the reassembled one. For the case of personal identity, Parfit (1984) develops such a response in detail. A related reaction would be to claim that if both competitors have equal claim to be the original, then neither *is* the original. If, however, one competitor is inferior,

then the other wins the day and counts as the original. It seems that on this view certain contingencies can establish or falsify identity claims. That conflicts with NI. Suppose that *w* is a possible world in which no ship is assembled from the discarded parts of the remodeled ship. In this world, then, the remodeled ship is the original. By NI, the restored ship and the original are identical in the actual world, contrary to the claim of the "best candidate" doctrine (which says that neither the remodeled nor the reassembled ship is the original). There are, however, more sophisticated "best candidate" theories that are not vulnerable to this objection (Nozick, 1982).

Some are convinced that the remodeled ship has the best claim to be the original, since it exhibits a greater degree of spatio-temporal continuity with the original (Wiggins, 1967). But it is unclear why the intuition that identity is preserved by spatio-temporal continuity should take precedence over the intuition that identity is preserved in the process of dismantlement and reassembly. Furthermore, certain versions of the ship of Theseus problem do not involve the feature that one of the ships competing to be the original possesses a greater degree of spatio-temporal continuity with the original than does the other (see below). Others are equally convinced that identity is *not* preserved by total part replacement. This view is often suggested blindly, as a stab in the dark, but there is in fact an interesting argument in its favor. Kripke (1980) argues that a table made out of a particular hunk of wood *could not* have been made out of a (totally) different hunk of wood. His reasoning is this: Suppose that in the actual world a table *T* is made out of a hunk of wood *H*; and suppose that there is a possible world *w* in which this very table, *T*, is made out of a different hunk of wood, H'. Then assuming that *H* and H' are completely unrelated (for example, they do not overlap), so that making a table out of the one is not somehow dependent upon making a table out of the other, there is another possible world w' in which *T*, as in the actual world, is made out of *H*, and another table T', exactly similar to *T*, is made out of H'. Since *T* and T' are not identical in w', it follows by ND that the table made out of H' in *w* is not *T*. Note, however, that the argument assumes that the table made out of H' in w' is the same table as the table made out of H' in *w*.

Kripke's reasoning can be applied to the present case (Kripke and others might dispute this claim; see below). Let *w* be a possible world just like the actual world in that *O*, the original ship, is manufactured exactly as it is in the actual world. In *w*, however, another ship, S', exactly similar to *O*, is simultaneously built out of precisely the same parts that *S*, the remodeled ship, is built out of in the actual world. Since S' and *O* are clearly different ships in *w*, it follows by ND that *O* and *S* are not the same ship in the actual world. Note again that the argument assumes that *S* and S' are the same ship, but it seems quite a stretch to deny that. Nevertheless, some have done so. Carter,1987 claims (in effect) that *S* and S' are not identical, but his argument simply *assumes* that *O* and *S* are the same ship. Alternatively, one might view the (Kripkean) argument as showing only that while *S* is the same ship as *O* in the actual world, *S* (that is, S') is not the same ship as *O* in *w*. But this is not an option for one who adheres to the standard account and hence adheres to ND. In defending this view, however, Gallois, (1986, 1988) suggests a weakened notion of rigid designation and a corresponding weakened formulation of ND. (See Carter, (1987) for criticism of Gallois' proposals. See also Chandler, 1975 for a precursor of Gallois' argument.)

If we grant that *O* and *S* cannot be the same ship, we seem to have a solution to the ship of Theseus paradox. By the Kripkean argument, only the reassembled ship has any claim to being the original ship, *O*. But this success is short lived. For we are left with the following additional paradox: Suppose that *S*

eventuates from *O* by replacing one part of *O* one day at a time. There seems to be widespread agreement that replacing just one part of a thing by a new exactly similar part preserves the identity of the thing. If so, then, by the transitivity of identity, *O* and *S* must be the same ship. It follows that either the Kripkean argument is incorrect, or replacement of even a single part (or small portion) does not preserve identity (a view known as "mereological essentialism;" Chisholm, 1973).

As indicated, Kripke denies that his argument (for the necessity of origin) applies to the case of change over time: "The question whether the table could have *changed* into ice is irrelevant here" (1972, 1980). So the question whether *O* could change into *S* is supposedly "irrelevant." But Kripke does not give a reason for this claim, and if cases of trans-temporal identity and trans-world identity differ markedly in relevant respects -- repsects relevant to Kripke's argument for the necessity of origin, it is not obvious what they are. (But see Forbes, 1985, and Lewis, 1986, for discussion.) The argument above was simply that *O* and *S* cannot be the same ship since there is a possible world in which they differ. If this argument is incorrect it is no doubt because there are conclusive reasons showing that *S* and S' differ. Even so, such reasons are clearly not "irrelevant." One may suspect that, if applied to the trans-temporal case, Kripke's reasoning will yield an argument for mereological essentialism. Indeed, a trans-world counterpart of such an argument has been tried (Chandler, 1976, though Chandler views his argument somewhat differently). In its effect, this argument does not differ essentially from the "paradox" sketched in the previous paragraph (which may well be viewed as an argument for mereological essentialism). Subsequent commentators, e.g., Salmon, (1979) and Chandler (1975, 1976), do not seem to take Kripke's admonition of irrelevance seriously.

In any case, there *is* a close connection between the two issues (the ship of Theseus problem and the question of the necessity of origin). This can be seen (though it may already be clear) by considering a modified version of the ship of Theseus problem. Suppose that when *O* is built, another ship O', exactly like *O*, is also built. Suppose that O' never sets sail, but instead is used as a kind of graphic repair manual and parts repository for *O*. Over time, planks are removed from O' and used to replace corresponding planks of *O*. The result is a ship *S* made wholly of planks from O' and standing (in the end), we may suppose, in exactly the place O' has always stood. Now do *O* and O' have equal claim to be *S*? And can we then declare that neither is *S*? Not according to the Kripkean line of thought. It looks for all the world as though the process of "remodeling" *O* is really just an elaborate means of dismantling and reassembling O'. And if O' and *S* are the same ship, then since *O* and O' are distinct, *O* and *S* cannot be the same ship.

This argument is vulnerable to the following two important criticisms: First, it conflicts with the common sense principle that (1) the material of an object can be totally replenished or replaced without affecting its identity (Salmon, 1979); and secondly, as mentioned, it conflicts with the additional common sense principle that (2) replacement by a single part or small portion preserves identity. These objections may seem to provide sufficient grounds for rejecting the Kripkean argument and perhaps restricting the application of Kripke's original argument for the necessity of origin (Noonan, 1983). There is, however, a rather striking problem with (2), and it is uncleear whether the conflict between (1) and the Kripkean argument should be resolved in favor of the former.

The problem with (2) is this. Pick a simple sort of objects, say, shoes, or better, sandals. Suppose *A* and *B* are two exactly similar sandals, one of which (*A*) is brand new and the other (*B*) is worn out. Each consists of a top strap and a sole, nothing more. If *B*'s worn strap is replaced by *A*'s new one, (2) dictates that the resulting sandal is *B* "refurbished." In fact, if the parts of *A* and *B* are simply exchanged, (2) dictates that that the sandal with the new parts, A', is *B* and the sandal with the old parts, B', is *A*. It follows by ND that *A* and A' and *B* and B' are distinct. This is surely the wrong result. The intuition that *A* and A' are the same sandal is very strong; and the process of exchanging the parts of *A* and *B* seems to amount to nothing more than the dismantling and reassembling of each. This example is no different in principle than the more elaborate trans-world cases discussed by Chisholm, (1967), Chandler, (1976), Salmon, (1979), or Gupta, (1980). (One who claims that *A* and A' differ in that A' comes into existence after *A*, does not have much to go on. *A* cannot be supposed to persist after A' comes into existence. We do not end up with two *new* sandals and one old one. Why then couldn't it be *A* itself that reappears at the later time?)

2.6 Church's Paradox

The following paradox -- perhaps the ultimate paradox of identity -- derives from an argument of Church (1982). Suppose Pierre thinks that London and Londres are different cities, but of course doesn't think that London is different from London, or that Londres is different from Londres. Assuming that proper names lack Fregean senses, we can apply LL to get the result that London and Londres *are* distinct. We have here an argument that, given the standard account of identity, merely *thinking* that *x* and *y* are distinct is enough to make them so. There are, of course, a number of ways around this conclusion without abandoning the standard account of identity. Church himself saw the argument (his version of it) as demonstrating the inadequacy of Russellian intensional logic -- in which variables and constants operate as they do in extensional logic, i.e., unequipped with senses. (For another reaction, see Salmon, 1986.) But there are strong arguments against the view that names (or variables) have senses (Kripke, 1980). In light of these arguments, Church's argument may be viewed as posing yet another paradox of identity.

The general form of Church's argument has been exploited by others to reach further puzzling conclusions. For example, it has been used to show that there can be no such thing as vague or "indeterminate" identity (Evans, 1978; and for discussion, Parsons 2000). For *x* is not vaguely identical to *x*; hence, if *x* is assumed to be vaguely identical to *y*, then by LL, *x* and *y* are (absolutely) distinct. As it stands, Evans' argument shows at best that vaguely identical objects must be absolutely distinct, not that there is no such thing as vague identity. But some have tried to amend the argument to get Evans' conclusion (Parsons, 2000; and see the entry on vagueness). In any case, it is useful to see the connection between Evans' argument and Church's. If, for example, 'vaguely identical' is taken to mean 'thought to be identical', then the two arguments collapse into one another. Church's line of argument would seem to lead ultimately to the extreme antirealist position that any perceived difference among objects is a real difference. If one resolves not to attempt to escape the clutches of LL by some clever dodge -- by disallowing straightforward quantifying-in, for example, as with the doctrine of Abelardian predicates -- one comes quickly to the absurd conclusion that no statement of the form $x = y$, where the terms are different, or are just different tokens of the same type, can be true. Yet it might just be that the fault lies

not in ourselves, but in LL.

3. Relative Identity

The fundamental claim of relative identity-the claim the various versions of the idea have in common-is that, as it seems in the passenger/person case, it can and does happen that *x* and *y* are the same *F* and (yet) *x* and *y* are not the same G. Now it is usually supposed that if *x* and *y* are the same *F* (G etc.), then that implies that *x* and *y* are *F*s (*G*s, etc.) If so, then the above schema is trivially satisfied by the case in which *x* and *y* are the same person but *x* (*y*) is not a passenger at all. But let us resolve to use the phrase '*x* and *y* are different *G*s' to mean '*x* and *y* are *G*s and *x* and *y* are not the same *G*'. Then the nontrivial core claim about relative identity is that the following may well be true:

> **(RI)**: *x* and *y* are the same *F* but *x* and *y* are different *G*s.

RI is a very interesting thesis. It seems to yield dramatically simple solutions to (at least some of) the puzzles about identity. We appear to be in a position to assert that young Oscar and old Oscar are the same dog but nonetheless distinct "temporary" objects; that Oscar and Oscar-minus are the same dog but different dog parts; that the same piece of clay can be now (identical to) one statue and now another; that London and Londres are the same city but different "objects of thought," and so forth. Doubts develop quickly, however. Either the *same dog* relation satisfies LL or it does not. If it does not, it is unclear why it should be taken to be a relation of *identity*. But if it satisfies LL, then it follows, given that Oscar and Oscar-minus are different dog parts, that Oscar-minus is not the same dog part as Oscar-minus. Furthermore, assuming that the *same dog part* relation *is* reflexive, it follows from the assumption that Oscar-minus and Oscar-minus are the same dog (and that LL is in force), that Oscar and Oscar-minus are indeed the same dog part, which in fact they are not.

It may seem, then, that RI is simply incoherent. These arguments, however, are a bit too quick. On analysis, they show only that the following three conditions form an inconsistent triad: (1) RI is true (for some fixed predicates *F* and *G*). (2) Identity relations are equivalence relations. (3) The relation *x and y are the same F* figuring in (1) satisfies LL. For suppose that the relation *x and y are the same G*, figuring in (1), is reflexive and that *x* is a *G*. Then *x* is the same *G* as *x*. But according to (1), *x* and *y* are not the same *G*s; hence, according to (3), it is not the case that *x* and *y* are the same *F*; yet (1) asserts otherwise. Now, most relative identity theorists maintain that while identity relations are equivalence relations, they do not in general satisfy LL. However, according to at least one analysis of the passenger/person case (and others), the *same person* relation satisfies LL but the *same passenger* relation is not straightforwardly an equivalence relation (Gupta, 1980). It should be clear though that this view is incompatible with the principle of the *identity of indiscernibles*: If *x* and *y* are different passengers, there must be, by the latter principle, some property *x* possesses that *y* does not. Hence if the *same person* relation satisfies LL, it follows that *x* and *y* are *not* the same person. For the remainder we will assume that identity relations are equivalence relations. Given this assumption, (and assuming that the underlying propositional logic is classical -- cf. Parsons, 2000) RI and LL are incompatible in the sense that within the framework of a single fixed language for which LL is defined, RI and LL are incompatible.

Yet the advocate of relative identity cannot simply reject any form of LL. There are true and indispensable instances of LL: If *x* and *y* are the same dog, then, surely, if *x* is a Dalmatian, so is *y*. The problem is that of formulating and motivating *restricted* forms of LL that are nonetheless strong enough to bear the burden of identity claims. There has been little systematic work done in this direction, crucial though it is to the relative identity project. (See Deutsch, 1997 for discussion of this issue.) There are, however, equivalence relations that do satisfy restricted forms of LL. These are sometimes called 'congruence relations' and they turn up frequently in mathematics. For example, say that integers *n* and *m* are congruent if their difference $n - m$ is a multiple of 3. This relation preserves multiplication and addition, but not every property. The numbers 2 and 11 are thus congruent but 2 is even and 11 is not. There are also non-mathematical congruencies. For example, the relation *x and y are traveling at the same speed* preserves certain properties and not others. If objects *x* and *y* are traveling at the same speed and *x* is traveling faster than *z*, the same is true of *y*. Such similarity relations satisfy restricted forms of LL. In fact, any equivalence relation satisfies a certain minimal form of LL (see below).

There are strong and weak versions of RI. The weak version says that RI has some (in fact, many) true instances but also that there are predicates *F* such that if *x* and *y* are the same *F*, then, for any equivalence relation, *E*, whatsoever (whether or not an identity relation), $E(x,y)$. This last condition implies that the relation *x and y are the same F* satisfies LL. The relation *P* defined so that $P(x,y)$ if and only if $H(x)$ and $H(y)$, where *H* is some predicate, is an equivalence relation. Hence, if *H* holds of *x* but not of *y*, there is an equivalence relation (namely, $P(x,y)$) that fails to hold of *x* and *y*. If we add that in this instance '*x* and *y* are the same *F*' is to be interpreted in terms of the relation $I(A,x,y)$, then the weak version of RI says that there is such a thing as relative identity and such a thing as absolute identity as well. The strong version, by contrast, says that there are (many) true instances of RI but there is no such thing as absolute identity. It is difficult to know what to make of the latter claim. Taken literally, it is false. The notion of unrestricted identity (in the sense of 'unrestricted' explained in §1) is demonstrably coherent. We return to this matter in §5 .

The puzzles about identity outlined in §2 (and there are many others, as well as many variants of these) put considerable pressure on the standard account. A theory of identity that allows for instances of RI is an attractive alternative (see below §4). But there is a certain kind of example of RI, frequently discussed in the literature, that has given relative identity something of a bad name. The passenger/person example is a case in point. The noun 'passenger' is derived from the corresponding relational expression 'passenger in (on) ...'. A passenger is someone who is a passenger in some vehicle (on some flight, etc.). Similarly, a father is man who fathers someone or who is the father of someone. This way of defining a kind of things from a relation between things is perfectly legitimate and altogether open-ended. Given any relation *R*, we can define 'an R' to apply to anything *x* that stands in *R* to something *y*. For example, we can define a 'schmapple' to be an apple in a barrel. All this is fine. But we can't *infer* from such a definition that the same apple might be two different schmapples. From the fact that someone is the father of two different children, we don't judge that he is two different fathers. The fact that airlines choose to count passengers as they do, rather than track persons, is their business, not logic's.

However, when *R* is an equivalence relation, we are entitled to such an inference. Consider the notorious

case of "surmen" (Geach, 1967). A pair of men are the "same surman" if they have the same surname; and a surman is a man who bears this relation to someone. So now it appears that that two different men can be the same surman, since two different men can have the same surname. As Geach (1967) insists (also Geach, 1973), surmen are *defined* to be men, so they are not merely classes of men. Hence we seem to have an instance of RI, and obviously any similarity relation (e.g., *x* and *y* have the same shape) will give rise to a similar case. Yet such instances of RI are not very interesting. It is granted all around that when ‘*F*’ is adjectival, different *G*s may be the same *F*. Different men may have the same surname, different objects, the same color, etc. Turning an adjectival similarity relation into a substantival one having the form of an identity statement yields an identity statement in name only.

A word about the point of view of those who subscribe to the weak version of RI. The view (call it the ‘weak view’) is that ordinary identity relations concerning (largely) the world of contingency and change are equivalence relations answering to restricted forms of LL. The exact nature of the restriction depends on the equivalence relation itself, though there is an element of generality. The kinds of properties preserved by the *same dog* relation are intuitively the same *kinds* of properties as are preserved by the *same cat* relation. From a logical point of view the best that can be said is that any identity relation, like any equivalence relation, preserves a certain minimal set of properties. For suppose *E* is some equivalence relation. Let *S* be the set containing all formulas of the form $E(x,y)$, and closed under the formation of negations, conjunctions, and quantification. Then *E* preserves any property expressed by a formula in *S*. Furthermore, on this view, although absolutely distinct objects may be the same *F*, absolutely identical objects cannot differ at all. Any instance of RI implies that
x and *y* are absolutely distinct.

4. The Paradoxes Reconsidered

Let us look back at the paradoxes of identity outlined in §2 from the perspective of the weak view regarding relative identity. That view allows that absolutely distinct objects may be the same *F*, but denies that absolutely identical objects can be different *G*’s. This implies that if *x* and *y* are relatively different objects, then *x* and *y* are absolutely distinct, and hence only pairs of absolutely distinct objects can satisfy RI. If *x* and *y* are absolutely distinct, we shall say that *x* and *y* are distinct ‘logical objects’; and similarly, if *x* and *y* are absolutely identical objects, then *x* and *y* are identical logical objects. The term ‘logical object’ does not stand for some new and special kind of thing. Absolutely distinct apples, for example, are distinct logical objects.

The following is the barest sketch of relativist solutions to the paradoxes of identity discussed in §2. No attempt is made to fully justify any proposed solution, though a modicum of justification emerges in the course of §6. It should be kept in mind that some of the strength of the relativist solutions derives from the weaknesses of the absolutist alternatives, some of which are discussed in §2.

4.1 The Paradox of Change

Young Oscar and old Oscar are the same dog but absolutely different things, i.e. different logical objects.

The material conditions rendering young Oscar and old Oscar the same dog (and the same Dalmatian) are precisely the same as the material conditions under which young Oscar and old Oscar would qualify as temporal parts of the same dog. The only difference is *logical*. The identity relation between young Oscar and old Oscar can be formalized in an extensional logic (Deutsch, 1997), but a theory of temporal parts requires a modal/temporal apparatus. Young Oscar is wholly present during his youth and possesses the simple, non-relational, property of not having a gray muzzle.

4.2 Chrysippus' Paradox

Oscar and Oscar-minus both survive Oscar's loss of a tail. At both t and t' Oscar and Oscar-minus are the same dog, but at t, Oscar and Oscar-minus are distinct logical objects. This implies (by ND) that Oscar and Oscar-minus are distinct logical objects even at t' Hence, we must allow that distinct logical objects may occupy the same space at the same time. This is not a problem, however. For although Oscar and Oscar-minus are distinct logical objects at t', they are physically coincident.

4.3 The Paradox of 101 Dalmatians

The relativist denies that dogs are "maximal." It is not true that no proper part of a dog is dog. All the 101 (and more) proper parts of Oscar differing from him and from one another by a hair are dogs. In fact, many (though of course not all) identity preserving changes Oscar might undergo correspond directly to proper parts of (an unchanged) Oscar. But there is no problem about barking in unison, and no problem about acting independently. All 101 are the same dog, despite their differences, just as young Oscar and old Oscar are the same dog, . The relativist denies that the dogs are many rather than deny that the many are dogs (Lewis, 1993).

4.4 The Paradox of Constitution

Constitution is identity, *absolute* identity. The relation between the piece of clay c and the statue s_1 on day 1 is one of absolute identity. So we have that $c = s_1$ on day 1, and for the same reason, $c = s_2$ on day 2. Furthermore, since s_1 and s_2 are different statues, it follows (on the weak view) that $s_1 \neq s_2$. In addition, the piece of clay c constituting s_1 on day 1 is (relatively) the same piece of clay as the piece of clay constituting s_2 on day 2. (The identity is relative because we have distinct objects -- the two statues -- that are the same piece of clay.) It follows that *no name of the piece of clay c can be a rigid designator in the standard sense*. That is, no name of c denotes absolutely the same thing on day 1 and on day 2. For on day 1, a name of the piece of clay c would denote s_1 and on day 2, it would denote s_2, and s_1 and s_2 are absolutely distinct. Nevertheless, a name of the piece of clay may be *relatively rigid*: it may denote at each time the *same piece of clay*. Although no name of the piece of clay c is absolutely rigid, that does not prevent the introduction of a name of c that denotes c at any time (or possible world). (Kraut, 1980 discusses a related notion of relative rigidity.)

There is, however, a certain ambiguity in the notion of a name of the piece of clay, inasmuch as the piece of clay may be any number of absolutely distinct objects. The notion of relative rigidity presupposes that a name for the piece of clay refers, with respect to some parameter *p*, to whatever object counts as the piece of clay relative to that parameter. This may be sufficient in the case of the piece of clay, but in other cases it is not. With respect to a fixed parameter *p* there may be no unique object to serve as the referent of the name. For example, if any number of dog parts count, at a fixed time, as the same dog, then which of these objects serves as the referent of 'Oscar'? We shall leave this question open for the time being but suggest that it may be worthwhile to view names such as 'Oscar' as *instantial* terms -- terms introduced into discourse by means of existential instantiation. The name 'Oscar' might be taken as denoting a representative member of the equivalence class of distinct objects qualifiying as the same dog as Oscar. It would follow, then, that most ordinary names are instantial terms. (An alternative is that of Geach, 1980, who draws a distinction between a *name of* and a *name for an* object; see Noonan, 1997 for discussion of Geach's distinction.)

4.5 The Ship of Theseus Paradox

In this case, the relativist, as so far understood, may seem to enjoy no advantage over the absolutist. The problem is not clearly one of reconciling LL with ordinary judgments of identity, and the advantage afforded by RI does not seem applicable. Griffin (1977), for example, relying on RI, claims that the original and remodeled ship are the same ship but not the same collection of planks, whereas the reassembled ship is the same collection of planks as the original but not the same ship. This simply doesn't resolve the problem. The problem is that the reassembled and remodeled ships have, *prima facie*, equal claim to be the original and so the bald claims that the reassembled ship is not--and the remodeled ship is--the original are unsupported. The problem is that of reconciling the intuition that certain small changes (replacement of a single part or small portion) preserve identity, with the problem illustrated by the sandals example of §2.5. It turns out, nevertheless, that the problem *is* one of dealing with the excesses of LL. To resolve the problem, we need an additional level of relativity. To motivate this development, consider the following abstract counterpart of the sandals example:

On the left there is an object P composed of three parts, P_1, P_2, and P_3. On the right is an exactly similar but non-identical object, Q, composed of exactly similar parts, Q_1, Q_2, and Q_3, in exactly the same arrangement. For the sake of illustration, we adopt the rule that only replacement of (at most) a *single* part by an exactly similar part preserves identity. Suppose we now interchange the parts of P and Q. We begin by replacing P_1 by Q_1 in P and replacing Q_1 by P_1 in Q, to obtain objects P^1 and Q^1. So P^1 is composed of parts Q_1, P_2, and P_3, and Q^1 is composed of parts P_1, Q_2, and Q_3. We then replace P_2 in P^1 by Q_2, to obtain P^2, and so on. Given our sample criterion of identity, and assuming the transitivity of identity, P and P^3 are counted the same, as are Q and Q^3. But this appears to be entirely the wrong result. Intuitively, P and Q^3 are the same, as are Q and P^3. For P and Q^3 are composed of exactly the same parts put together in exactly the same way, and similarly for Q and P^3. Futhermore, Q_3 (P_3) can be viewed as simply the result of taking P (Q) apart and putting *it* back together in a slightly different location. And this last difference can be eliminated by switching the locations of P^3 and Q^3 as a last step in the process.

Suppose, however, that we replace our criterion of identity by the following more complicated rule: *x* and *y* are the same *relative to z*, if both *x* and *y* differ from *z* at most by a single part. (This relation is transitive, and is in fact an equivalence relation.) For example, *relative to P*, *P*, P^1, Q^2, and Q^3 are the same, but *Q*, Q^1, P^2 and P^3, are not. Of course, replacement by a single part is an artificial criterion of identity. In actual cases, it will be a matter of the degree or kind of deviation *from the original* (represented by the third parameter, *z*). The basic idea is that identity through change is not a matter of identity through successive, accumulated changes -- that notion conflicts with both intuition (e.g., the sandals example) and the Kripkean argument: Through successive changes objects can evolve into *other* objects. The three-place relation of idenitity does not satisfy LL and is consistent with the outlook of the relativist. Gupta, (1980) develops a somewhat similar idea in detail. Williamson (1990) suggests a rather different approach, but one that, like the above, treats identity through change as an equivalence relation that does not satisfy LL.

4.6 Church’s Paradox

Church’s argument implies that if Pierre’s doxastic position is as described (in §2.6), then London and Londres are distinct objects. Assuming the standard account of identity, the result is that either Pierre’s doxastic position *cannot* be as described or else London and Londres are different *cities* (or else we must punt). Since London and Londres are not different cities, the standard account entails that Pierre’s doxastic position cannot be as described (or else we must punt). This was Church’s own position as regards certain puzzles about synonymy, such as Mate’s puzzle (Mates, 1952). Church held that one who believes that lawyers are lawyers, must indeed believe that lawyers are attorneys, despite any refusal to assent to (or desire to dissent from) ‘Lawyers are attorneys’ (Church, 1954). Kripke later argued (Kripke, 1979) that assent and failure to assent must be taken at face value (at least in the case of Pierre) and Pierre’s doxastic position is as described. Kripke chose to punt -- concluding that the problem is a problem for any "logic" of belief. The relativist concludes instead that (a) Pierre’s doxastic position is as described, (b) if so, London and Londres are distinct objects, and (c) London and Londres are nonetheless the same city. Whether this resolution of Church’s paradox can be exploited to yield solutions to Frege’s puzzle (Salmon, 1986) or Kripke’s puzzle (1979) remains to be seen. Crimmins (1998) has recently suggested that the analysis of propositional attitudes requires a notion of "semantic pretense." In reporting Pierre’s doxastic position we engage in a pretense to the effect that London and Londres are different cities associated with different Fregean senses. Crimmins’ goal is to reconcile (a), (c) and the following, (d): that the pure semantics of proper names (’London’, ‘Londres’) is Millian or directly referential (Kripke, 1979). The relativist proposes just such a reconciliation but suggests that the pretense can be dropped.

5. Absolute Identity

The philosopher P.T. Geach first broached the subject of relative identity and introduced the phrase ‘relative identity’. Over the years, Geach has suggested specific instances of RI (a variant of the case of Oscar and his tail is due to Geach (Geach, 1980)) and in this way he has contributed to the development

of the weak view concerning relative identity, i.e. the view that while ordinary identity relations are often relative, some are not. But Geach maintains that absolute identity does not exist. What is his argument?

That is hard to say. Geach sets up two strawman candidates for absolute identity, one at the beginning of his discussion and one at the end, and he easily disposes of both. In between he develops an interesting and influential argument to the effect that identity, *even as formalized in the system* $FOL^=$, is relative identity. However, Geach takes himself to have shown, by this argument, that absolute identity does not exist. At the end of his initial presentation of the argument in his 1967 paper, Geach remarks:

> We thought we had a criterion for a predicable's expressing strict identity [i.e., as Geach says, "strict, absolute, unqualified identity"] but the thing has come apart in our hands; and no alternative rigorous criterion that could replace this one has thus far been suggested. (Geach, 1972, p. 241)

It turns out, as we'll see, that all that comes apart is the false notion that in $FOL^=$ the identity symbol *defines* the relation $I(A,x,y)$. Let us examine Geach's line of reasoning in detail, focusing on the presentation in his 1967 article, the *locus classicus* of the notion of relative identity.

Geach begins by urging that a plain identity statement '*x* and *y* are the same' is in need of a completing predicate: '*x* and *y* are the same *F*'. Frege had argued that statements of number such as 'this is one' require a completing predicate: 'this is one *F*', and so it is, Geach claims, with identity statements. This is a natural view for one who subscribes to RI. The latter cannot even be stated without the completing predicates. Nevertheless, both the claim itself and the analogy with Frege have been questioned. Some argue that the analogy with Frege is incorrect, others that while the analogy is correct, both Frege and Geach are wrong (Perry, 1978 and Bennett and Alston, 1984). These matters will be discussed in greater detail in an updated version of this article. They do not bear directly on the question of the coherence and truth of RI or the question of absolute identity. One who adopts the weak view would not want to follow Geach on this score. And one could maintain the "completing thesis" without being committed to RI. Furthermore, the completing thesis occupies a puzzling role in Geach's dialectic. Immediately following his statement of the thesis, Geach formalizes $FOL^=$ on the basis of the single formula:

> **(W)**: $\wp(a) \leftrightarrow \exists x(\wp(x) \wedge x = a)$

(The 'W' is for Hao Wang, who first suggested it. The reader is invited to prove Ref and LL from W.) But we hear no complaint about the syntax of W despite its involving a seemingly unrelativized identity symbol. It turns out, however, that Geach apparently thinks of the completing predicate as being given by the whole descriptive apparatus of *L* or a fragment thereof.

Geach now observes

> ... if we consider a moment, we see that an *I*-predicable in given theory *T need not* express strict, absolute, unqualified identity; it need mean no more than that two objects are

> indiscernible by the predicables that form the descriptive resources of the theory -- the ideology of the theory ... . (p. 240)

Here an ‘I-predicable’ is a binary relation symbol ‘=’ satisfying (W). Geach’s focus at this point is on the need to relativize an *I*-predicable to a theory *T*. Geach then immediately saddles the friend of absolute identity with the view that for "real identity" we need not bring in the ideology of a definite theory. This is Geach’s first strawman. When logicians, in discussing FOL$^=$, speak of "real identity" -- and they often do (see Enderton 2000 or Silver 1994, for example) -- they do not mean a relation of *universal identity*, since the universal set does not exist. Nor do they intend, in formulating LL, to use ‘true of’ in a completely unrestrained way which gives rise to semantic paradox. It is no argument against those who wish to distinguish mere indiscernibility from real identity to say that they "will soon fall into contradictions," e.g., Grelling’s or Russe LL's. The relation *I*(*A*,*x*,*y*) is sufficiently relativized. (It is relativized to a *set A*.)

We come next to the main point:

> Objects that are indiscernible when we are confined to the ideology of T may perfectly well be discernible in ideology of a theory T^1 of which T is a fragment. (p. 240)

The warrant for this claim can only be the language relativity of identity when treated as a non-logical notion (see §1). That this is what Geach has in mind is clear from some approving remarks he makes in his 1973 article about Quine’s (1970) proposal to treat identity as a non-logical notion. But how does it follow that absolute identity does not exist? Geach seems to think that the defender of absolute identity will look to Ref and LL (or W) -- and not beyond -- for a full account of "strict, absolute, unqualified" identity. That is not so. The fact that these formulas in themselves define only indiscernibility relations is a logical commonplace. So this is Geach’s second strawman.

Is Geach’s argument at least an argument that identity is relative? Does language relativity support the conclusion that RI is true even of identity as formalized in FOL$^=$? The general idea appears to be that language relativity suggests that we take identity *to be* indiscernibility, and conclude that objects identical relative to one ideology *F* may be different relative to another ideology *G*, and that this confirms RI. Notice first of all that this argument relies on the identity of indiscernibles: that indiscernibility implies identity. This principle is not valid in FOL$^=$ even when the latter is treated as a proper theory. Language relativity does not imply that the distinctness of distinct objects cannot go unnoticed.

Secondly, the interesting cases of RI do not involve a shift from an impoverished point of view to an improved one -- whether this is seen in epistemic terms (which Geach disputes -- Geach, (1973)) or in purely logical terms. We do not affirm that old Oscar and young Oscar, for example, are the same dog on the grounds that there is an ideology with respect to which old Oscar and young Oscar are indistinguishable. Such an ideology would be incapable of describing any change in Oscar. It is true that the *same dog* relation determines a set of predicates that do not discriminate between the members of certain pairs of dogs -- the dogs in the photographs mentioned in earlier, for example. And it is true that

these predicates determine a sublanguage in which the *same dog* relation is a congruence, i.e. no predicate of the sublanguage distinguishes *x* from *y*, if *x* and *y* are the same dog. But the very *sense* of such statements as that old Oscar and young Oscar are the same dog requires a language in which a change in Oscar is expressible. We are talking, after all, about *old* Oscar and *young* Oscar. If we take seriously the idea that change involves the application of incompatible predicates, then the sublanguage cannot express the contrast between old Oscar and young Oscar.

Third, the phenomenon of language relativity (in the technical sense discussed in §1) has led many philosophers, including Geach, to the view that ideology creates ontology. There is no antecedently given domain of objects, already individuated, and waiting to be described. Instead, theories carve up the world in various ways, rendering some things noticeably distinct and others indiscernible, depending on a theories' descriptive resources. The very notion of *object* is theory-bound (Kraut, 1980). This sort of anti-realism may seem to go hand in hand with relative identity. Model theory, however, is realist to its core and language relativity is a model-theoretic phenomenon. It is a matter of definability (in a structure). Referring back to §1, in order to make sense of language relativity we have to start with a pair of *distinct* objects, *a* and *b*, (distinct from the standpoint of the metalanguage), and hence a pair of objects we assume are already individuated. These objects, however, are indistinguishable in *M*, since no formula of L' defines a subset of *M* containing the one object and not the other. When we move to M', we find that there is a formula of the enriched language that defines such a subset in M'. Thus, language relativity is not really any sort relativity of *identity* at all. We must assume that the objects *a* and *b* are distinct in order to *describe* the phenomenon. If we are living in *M*, and suspect that Martians living in M' can distinguish *a* from *b*, our suspicion is not merely to the effect that Martians carve things up differently than we do. Our own model theory tells us that there is more to it than that. Our suspicion must be to the effect that *a* and *b are* absolutely distinct. If we are blind to the difference between *a* and *b*, but the Martians are not, then there must be a difference; and even if we are living in *M*, we know there's a difference, or at least we can suspect there is, since model theory tells us that such suspicion is well founded.

Let us go back to Geach's remark that we "*need not*" interpret identity absolutely. While this is true, we need not interpret it as indiscernibility either. There are always the quotient structures (Quine, 1963) . Instead of taking our "reality" to be *M*, and our "identity" to be indiscernibility in *M*, we can move to the quotient structure, *QM*, whose elements are the equivalence classes, [*x*], for *x* in *M*. If *x* and *y* are indiscernible in *M*, then in *QM*, [*x*] and [*y*] are absolutely identical. We can do this even if we wish to treat $FOL^=$ as a proper theory. For example, suppose L' is a language in which people having the same income are indiscernible. The domain of *M* now consists of people. *QM*, however, consists of income groups, equivalence classes of people having the same income, and identity in *QM* is absolute. Geach objects to such reinterpretation in terms of the quotient structures on the grounds that it increases the ontological commitments not only of L' but of any language of which L' is a sublanguage.

Let's focus on L' first. From a purely model-theoretic point of view the question is moot. We cannot deny that *QM* is a structure for L'. Thus, L' is committed to people *vis à vis* one structure and to income groups *vis à vis* the corresponding quotient structure. But let's pretend that the structures are "representations of reality," and so the question now becomes: Which representation is preferable? Is there then any reason to prefer the ontology of *M* to that of *QM*? *M* contains people but no sets of people, whereas *QM* contains

sets of people but no people. By Quine's criterion of ontological commitment -- that to be is to be the value of a variable -- commitment to a set of objects does not carry a commitment to its elements. That is one of the odd consequences of Quine's criterion. Unless there is some ontological reason to prefer people to sets of people (perhaps because sets are never to be preferred), the ontologies of *M* and *QM* seem pretty much on a par. Both commit L' to one kind of thing.

Geach makes the additional claim that the ontological commitments of a sublanguage L' of a language *L* are inherited by *L* (Geach, 1973). Suppose then that *L* is a language containing expressions for several equivalence relations defined on people: say, *same income*, *same surname*, and *same job*. Geach argues that *L* need only be committed to the existence of people. Things such as income groups, job groups (equivalence classes of people with the same job), and surmen can all be counted using the equivalencies, without bringing surmen, job groups, and income groups into the picture. Consider any sublanguage for which any one of these equivalence relations is a congruence, i.e. for which LL$'$ holds. Pick the language, L_1, for example, in which people having the same job are indiscernible. More precisely, we assume that T_1 is the pure theory with identity whose ideology is confined to the language L_1. Let M_1 be a model of T_1. We may imagine the domain of M_1 to consist of people, and we can interpret indiscernibility in M_1 to be the relation *x and y have the same job*. Geach would argue that if L_1 is committed to the elements of QM_1 -- the job groups -- then so is *L*. But that is not true. If *T* is a theory of the three distinct equivalence relations formulated in *L*, the most *T* (or *L*) would be committed to are the partitions determined by the equivalence relations; and in any case, it would be perfectly consistent to insist that, whatever the ontological commitments of L_1, reality, as described by *L*, consists of people.

The foregoing considerations are rather abstract. To see more clearly what is at stake, let us focus on a specific example. Geach (1967) mentions that rational numbers are defined set-theoretically to be equivalence classes of integers determined by a certain equivalence relation defined on "fractions," i.e. ordered pairs of integers (1/2 is <1,2>, 2/4 is <2,4>, etc.). He suggests that we can instead construe our theory of rational numbers to be about the fractions themselves, taking the *I*-predicable of our theory to be the following equivalence relation, *E*:

(R): $E(\langle x,y\rangle, \langle u,v\rangle)$ iff $xv = yu$.

This approach, Geach says, would have "the advantage of lightening a theory's set-theoretical burdens. (In our present example, we need not bring in *infinite sets* of ordered pairs of integers into the theory of rationals.)."

The first thing to notice about this example is that *E cannot* be the I-predicable of such a theory, since *E* is *defined* in terms of identity (look at the right side of R). It is '=' that must serve as the *I*-predicable, and it renders distinct ordered pairs of integers discernible. The moral is that not all equivalence relations can be drafted to do the job of identity, even given a limited ideology. There is, indeed, a plausible argument that *any* equivalence relation presupposes identity -- not necessarily in the direct way illustrated by (R), but indirectly, nonetheless (see §6). Moreover, from the standpoint of general mathematics, once we have (R), we have the (infinite) equivalence classes it determines and the partition it induces. These are

inescapable. Even from a more limited viewpoint, it seems that once we have enough set theory to give us ordered pairs of integers and the ability to define (R), we get the partition it induces as well.

Geach perceives an ontological advantage in relative identity; but his argument is unconvincing. Shifting to the quotient structures, as Quine suggested, does not induce a "baroque, Meinongian ontology" (Geach, 1967). In particular, the "home language" (L) does not inherit the commitment of the fragment (L_1), and the ontology of an arbitrary model of the pure theory of identity based on the latter language is at least no more various than that of the corresponding quotient model. There are, however, a number of ways in which relative identity does succeed in avoiding commitment to certain entities required by its absolute rival. These are discussed in the replies to objections 4 and 5 in the next section.

6. Objections and Replies

The following constitute a "start up" set of objections and replies concerning relative identity and/or aspects of the foregoing account of relative identity and its rival. Time and space constraints prevent a more extended initial discussion. In addition, there is no presumption that the objections discussed below are the most important or that the initial replies to them are without fault. It is hoped that the present discussion will evolve into a more full blown one, involving contributions by the author and readers alike. Should the discussion become lengthy, old or unchallenged objections and/or replies can be placed in the archives.

Objection 1: "Relativist theories of identity, all of which are inconsistent with Leibniz's principle [LL], currently enjoy little support. The doubts about them are (a) whether they really are theories of numerical identity, (b) whether they can be made internally consistent, and (c) whether they are sufficiently motivated." (Burke, 1994.)

Reply: In reverse order: (c) The issues discussed in §2 and §4 surely provide sufficient motivation. (b) No proof of inconsistency has ever been forthcoming from opponents of relative identity, and in fact the weak view is consistent inasmuch as it has a model in the theory of similarity relations. The arguments outlined in the second paragraph of §3 are frequently cited as showing that relative identity is incoherent; but they show only that RI is incompatible with (unrestricted) LL. (a) See the replies to objections 2 and 3 below.

Objection 2: If an identity relation obeys only a restricted form of LL -- if it preserves only *some* properties and not *all* -- then how do we *tell* which properties serve to individuate a pair of distinct objects?

Reply: Similarity relations satisfy only restricted forms of LL. How then do we *tell* which properties are preserved by the *same shape* relation and which are not? It is no objection to the thesis that identity relations in general preserve some properties and not others to demand to know which are which. At best the objection points to a problem we must face anyway (for the case of similarity). In general, a property is preserved by an equivalence relation if it "spreads" in an equivalence class determined by the relation:

If one member of the class has the property, then every member does. Every property spreads in a singleton, as absolute identity demands.

Objection 3: If identity statements are mere equivalencies, what distinguishes identity from mere similarity?

Reply: The distinction between identity and similarity *statements* (or sentences) is usually drawn in terms of the distinction between substantival and adjectival common nouns. If *F* is a common noun standing for a kind of *things* e.g., 'horse', then '*x* and *y* are the same *F*' is a statement of identity, whereas if *F* is an a common noun standing for a kind of *properties* of things, then '*x* and *y* are the same *F*' is a statement of similarity. (It's interesting to note that when the noun is proper, i.e. a proper name, the result is a statement of similarity, not identity -- as in 'He's not the same Bill we knew before'.) This distinction rests ultimately on the metaphysical distinction between substance and attribute, object and property. While the distinction no doubt presupposes the concept of individuation (the bundle theory, for example, presupposes that we have the means to individuate properties), there is no obvious reason to suppose that it entails the denial of RI, i.e. the claim that no instance of RI is true. For a beginner's review -- from an historical perspective -- of the issues concerning substance and attribute, see O'Connor, (1967); and for more recent and advanced discussion and bibliography, see the entry on properties.

Objection 4: Consider the following alleged instance of RI:

1. *A* is the same word type as *B*, but *A* and *B* are different word tokens.

"If '*A*' and '*B*' refer to the same objects throughout (1), the first conjunct of (1) is not an identity statement, and the counterexample (to the thesis that no instance of RI is true) fails. If both conjuncts are identity statements in the required sense, '*A*' and '*B*' must refer to word types in the first conjunct and word tokens in the second, and the counterexample fails" (Perry, 1970).

Reply: First, if "in the required sense" means "satisfies LL," then the objection buys correctness only at the price of begging the question. Advocates of relative identity will maintain that the relation *A is the same word type as B* is an identity relation, defined on tokens, that does not satisfy LL.

Secondly, even if one insists that in this case intuition dictates that if *A* and *B* refer to tokens in both conjuncts of (1), then '*A* is the same word type as *B*' expresses only the similarity relation: *A and B are tokens of the same type*, there are other cases where, intuitively, both conjuncts of RI involve identity relations and yet the relevant terms all refer to the same kind of things; for example,

2. *A* and *B* are the same dog but *A* and *B* are different physical objects,

as said of young Oscar and old Oscar. Here there is no temptation to suppose that the relation *A and B are the same dog* is *not* an identity relation. One may invoke a theory -- a theory of temporal parts, for example -- that construes the relation as a certain kind of similarity, but that is theory, not pretheoretical

intuition. It is no objection to the relativist's *theory*, which holds in part that '*A* and *B* are the same dog' expresses a relation of primitive identity, that there is an alternative theory according to which it expresses a similarity relation obtaining between two temporal parts of the same object. Furthermore, in the case of (2), *A* and *B* refer, again intuitively, to the same things in both conjuncts.

Third, there are cases in which the relative identity view does possess an ontological advantage. Consider

3. *A* and *B* are the same piece of clay but *A* and *B* are different statues.

Suppose *A* and *B* are understood to refer to one sort of thing -- pieces of clay -- in the first conjunct and another -- statues -- in the second conjunct. Assume that the piece of clay *c* denoted by *A* in the first conjunct constitutes, at time *t*, the statue *s*. Then assuming that statues are physical objects, there are two distinct physical objects belonging to different kinds occupying the same space at *t*. Some, notably Wiggins (1980), hold that this is entirely possible: Distinct physical objects may occupy the same space at the same time, provided they belong to different kinds. The temporal parts doctrine supports and encourages this view. A statue may be a temporal part of a temporally extended piece of clay. But one statue, it seems, cannot be a temporal part of another. Even so, however, the duality of constituter and thing constituted is unparsimonious (cf. Lewis, 1993), and the relativist is not committed to it.

Again, consider

4. *A* and *B* are the same book but *A* and *B* are different copies (of the book).

One can say that in the first conjunct, *A* and *B* refer to books (absolutely the same book), whereas in the second conjunct, *A* and *B* refer to (absolutely distinct) copies. But the alleged duality of books and copies of books is unparsimonious and the relativist is not committed to it. There is no reason to concede to the philosopher that we do not actually purchase or read *books*; instead we purchase and read only *copies* of books. Any copy of a book is just as much the "book itself" as is any other copy. Any copy of a book is *the same book* as any other copy. Nelson Goodman once remarked that "Any accurate copy of a poem is as much the original work as any other" (Goodman, 1968). Goodman was not suggesting that the distinction between poem and copy collapses. If it does collapse, however, we have an explanation of why any accurate copy is as much the original work as any other: any such copy is the same work as any other.

Objection 5: Geach remarks that "As for our recognizing relative identity predicables: any equivalence relation...can be used to specify a criterion of relative identity." But §3 above contains a counterexample. Some equivalence relations are defined in terms of the I-predicable of a theory and hence cannot serve as such. (Any pair of I-predicables for a fixed theory are equivalent.) In fact it seems that any equivalence relation presupposes identity (cf. McGinn, 2000). For example, the relation *x and y are the same color* presupposes identity of colors, since it means that there are colors C and C' such that x has C and y has C', and $C = C'$. Identity, therefore, is logically prior to equivalence.

Reply: This is a good objection. It does seem to show, as the objector says, that identity is logically prior to ordinary similarity relations. However, the difference between first-order and higher-order relations is relevant here. Traditionally, similarity relations such as *x and y are the same color* have been represented, in the way indicated in the objection, as higher-order relations involving identities between higher order objects (properties). Yet this treatment may not be inevitable. In Deutsch (1997), an attempt is made to treat similarity relations of the form '*x* and *y* are the same *F*' (where *F* is adjectival) as primitive, first-order, purely logical relations (see also Williamson, 1988). If successful, a first-order treatment of similarity would show that the impression that identity is prior to equivalence is merely a misimpression -- due to the assumption that the usual higher-order account of similarity relations is the only option.

Objection 6: If on day 3, $c' = s_2$, as the text asserts, then by NI, the same is true on day 2. But the text also asserts that on day 2, $c = s_2$; yet $c \neq c'$. This is incoherent.

Reply: The term s_2 is not an absolutely rigid designator and so NI does not apply.

Objection 7: The notion of relative identity is incoherent: "If a cat and one of its proper parts are one and the same cat, what is the mass of that one cat?" (Burke, 1994)

Reply: Young Oscar and Old Oscar are the same dog, but it makes no sense to ask: "What is the mass of that one dog." Given the possibility of change, identical objects may differ in mass. On the relative identity account, that means that distinct logical objects that are the same *F* may differ in mass -- and may differ with respect to a host of other properties as well. Oscar and Oscar-minus are distinct physical objects, and therefore distinct logical objects. Distinct physical objects may differ in mass.

Objection 8: We can solve the paradox of 101 Dalmatians by appeal to a notion of "almost identity" (Lewis, 1993). We can admit, in light of the "problem of the many" (Unger, 1980), that the 101 dog parts are dogs, but we can also affirm that the 101 dogs are not many; for they are "almost one." Almost-identity is not a relation of indiscernibility, since it is not transitive, and so it differs from relative identity. It is a matter of negligible difference. A series of negligible differences can add up to one that is not negligible.

Reply: The difference between Oscar and Oscar-minus is not negligible and the two are not almost-identical. Lewis concedes this point but proposes to combine almost-identity with supervaluations to give a mixed solution to the paradox. The supervaluation solution starts from the assumption that one and only one of the dog parts is a dog (and a Dalmatian, and Oscar), but it doesn't matter which. It doesn't matter which because we haven't decided as much, and we aren't going to. Since it is true that any such decision renders one and only one dog part a dog, it is plain-true, i.e. supertrue, that there is one and only one dog in the picture. But it is not clear that this approach enjoys any advantage over that of relative identity; in fact, it seems to produce instances of RI. Compare: Fred's bicycle has a basket attached to it. Ordinarily, our discourse slides over the difference between Fred's bicycle with its basket attached and Fred's bicycle minus the basket. (In this respect, the case of Fred's bicycle differs somewhat from that of Oscar and Oscar-minus. We tend not to ignore *that* difference.) In particular, we don't say that Fred has two bicycles

even if we allow that Fred's bicycle-minus is a bicycle. Both relative identity and supervaluations validate this intuition. However, both relative identity and supervaluations also affirm that Fred's bicycle and Fred's bicycle-minus are absolutely distinct objects. That is, the statement that Fred's bicycle and Fred's bicycle-minus are distinct is supertrue. So the supervaluation technique affirms both that Fred's bicycle and Fred's bicycle-minus are distinct objects *and* that there is one and only one (relevant) bicycle. That is RI, or close enough. The supervaluation approach is not so much an alternative to relative identity as a form of it.

The Definition of Morality

The term “morality” can be used either

1. descriptively to refer to a code of conduct put forward by a society or,
    a. some other group, such as a religion, or
    b. accepted by an individual for her own behavior or
2. normatively to refer to a code of conduct that, given specified conditions, would be put forward by all rational persons.

How morality is defined plays a crucial, although often unacknowledged, role in formulating ethical theories. To take “morality” to refer to an actually existing code of conduct is quite likely to lead to some form of relativism. Among those who use “morality” normatively, different specifications of the conditions under which all rational persons would put forward a code of conduct result in different kinds of moral theories. To claim that “morality” in the normative sense does not have any referent, that is, to claim that there is no code of conduct that, under any plausible specified conditions, would be put forward by all rational persons, results in moral skepticism. Thus, although, not widely discussed, the definition of morality has great significance for moral theory.

1. Descriptive Definitions of “morality”

“Morality” is an unusual word. It is not used very much, at least not without some qualification. People do sometimes talk about “Christian morality,” “Nazi morality,” or about “the morality of the Greeks,” but they seldom talk simply about morality all by itself. Anthropologists used to claim that morality, like law, applied only within a society. They claimed that “morality” referred to that code of conduct that is put forward by a society. This account seems to fit best those societies that have no written language,

where often no distinctions are made among morality, etiquette, law, and religion. But even for anthropologists “morality” does not often mean simply “code of conduct put forward by a society.” Often, morality is distinguished from etiquette, law, and religion, all of which provide codes of conduct put forward by a society.

Etiquette is sometimes included as a part of morality, but it applies to behavior that is considered less serious than the kinds of actions to which morality usually applies. Law is distinguished from morality by having explicit rules, penalties, and officials who interpret the laws and apply the penalties, but there is often considerable overlap in the conduct governed by morality and that governed by law. Religion differs from morality in that it includes stories, usually about supernatural beings, that are used to explain or justify the behavior that it requires. Although there is often a considerable overlap in the conduct required by religion and that required by morality, morality provides only a guide to conduct, whereas religion always contains more than this. When “morality” is used simply to refer to a code of conduct put forward by a society, whether or not it is distinguished from etiquette, law, and religion, then it is being used in a completely descriptive sense.

When “morality” is used in this descriptive way, moralities can differ from each other in their content and in the foundation that members of the society claim their morality to have. A society might have a morality that is primarily concerned with practices not related to other persons, e.g., which days must be devoted to certain rituals, and might claim that their morality, which is concerned primarily with ritual, is based on the commands of God. Or a society might have a morality that is concerned primarily with sexual practices, and claim that their morality, which has this concern, is based on human nature. Or a society might regard morality as being concerned primarily with practices that minimize the harms that people suffer and claim that their morality, which has this concern, is based on reason. Many societies have moralities that are concerned with all of the above and that are claimed to have all three of the above foundations. But, in this sense of “morality,” regardless of its content, or the justification that those who accept the morality claim for it, the only universal features that all moralities have is that they are put forward by a society and they provide a guide for the behavior of the people in that society. In this sense of “morality,” morality might allow slavery or might allow some people with one skin color to behave in ways that those with a different skin color are not allowed to behave. In this sense of “morality,” it is not even essential that morality incorporate impartiality with regard to all moral agents, those people whose behavior is subject to moral judgments, or that it be universalizable in any significant way.

Although most philosophers do not use “morality” in this purely descriptive sense, some philosophers do. Ethical relativists are interested in these different moralities and claim that they are only kind of morality there is. [Edward Westermarck, *Ethical Relativity*] They deny that there is any universal normative morality. Ethical relativists are not merely, or even primarily, making a linguistic claim about the proper use of the English word, “morality.” However, they hold that only when the term “morality” is used in this descriptive sense is there something that it actually refers to, namely, a code of conduct put forward by a society. They claim that if “morality” is taken to refer to a universal code of conduct that would be endorsed by all rational persons, then there is no referent for the term “morality.” Although ethical relativists admit that many speakers of English use “morality” to refer to such a universal code of

conduct, they claim such persons are mistaken in thinking that there is anything that is the referent of that sense of the word. Ethical relativists are primarily concerned with denying that there is any universal morality that should be used by people in all societies to guide their own conduct and to make judgments about the conduct of others.

When “morality” refers to the codes of conduct of different societies, the features that are essential are that morality is a code of conduct that is put forward by a society and that it is used as a guide to behavior by the members of that society. In this descriptive sense, “morality” can refer to codes of conduct of different societies with widely differing content, and still be used unambiguously. However, there are now other descriptive senses of “morality.” In the sense most closely related to the original descriptive sense, “morality” refers to a guide to behavior put forward by some group other than a society, for example, a religious group. When the guide to conduct put forward by a religious group conflicts with the guide to conduct put forward by a society, it is not clear whether to say that there are conflicting moralities, or that the code of the religious group conflicts with morality. People who are members of that society and also members of the religious group, might differ with regard to the guide that they accept. They are likely to regard the guide they accept as the true morality.

In small homogeneous societies people do not belong to groups which put forward guides to behavior that conflict with the guide put forward by their society. There is only one guide to behavior that is accepted by all members of the society and that is the code of conduct that is put forward by the society. For such societies there is no ambiguity about which guide “morality” refers to. However, in those large societies where people often belong to groups that put forward guides to behavior that conflict with the guide put forward by their society, they do not always accept the guide put forward by their society. If they accept the conflicting guide of some other group to which they belong, often a religious group, rather than the guide put forward by their society, they will not regard the guide put forward by their society as a true or genuine morality.

This reveals an ambiguity in the original descriptive sense of morality that has two essential features: that morality is a code of conduct that is put forward by a society and that it is used as a guide to behavior by the members of that society. This ambiguity was not recognized because of the concentration on small homogeneous societies. Does “morality” refer only to those guides to conduct put forward by a society, or does it refer to guides to conduct put forward by other groups as well? There is another related ambiguity if the “code of conduct put forward by a society” is not “used as a guide to behavior by the members of that society.” Which of these essential features is most essential? The recognition that people in a society do not always accept the code of conduct that is put forward by their society presents problems for the descriptive sense of “morality” as the code of conduct put forward by a society and which used as a guide to behavior by the members of that society.

However, it is not useful to adopt a definition of “morality” as meaning the code of conduct accepted by the members of a society because in many large societies, not all members of the society accept the same code of conduct. Nor is it useful to adopt a somewhat more general definition of “morality” as the code of conduct accepted by the members of a group because it is not only always possible, it is often the case, that not all members of any group accept the same code. A natural outcome of these problems is to

switch attention from groups to individuals. If what is important is what code of conduct people accept, and members of a group do not always accept the same code of conduct, then why be concerned with groups at all?

This consideration leads to a new descriptive sense of “morality.” “morality” is taken to mean that guide to behavior that is regarded by an individual as overriding and that he wants to be universally adopted. [See R. M. Hare, *Moral Thinking*] In this sense of “morality,” it refers to a guide to behavior accepted by an individual rather than that put forward by a society or any other group. But “morality” does not refer to just any guide to behavior accepted by an individual, it is that guide to behavior that the individual adopts as his overriding guide, and wants everyone else to adopt as their overriding guide as well. This sense of “morality” is a descriptive sense, because a person can refer to an individual’s morality without endorsing it. In this sense, like the original descriptive sense, morality has no limitations on content. Whatever guide to behavior an individual regards as overriding and wants to be universally adopted is that individual’s morality.

When people explicitly talk about the morality of a group other than their own or of a person other than themselves, it is usually clear that they are using “morality” in a descriptive sense. However, when a person simply claims that morality prohibits or requires a given action, then the term “morality” is genuinely ambiguous. It is not clear whether it refers to (1) a guide to behavior that is put forward by a society, either his own or some other society; (1a) a guide that is put forward by a group, either one to which he belongs or another; or (1b) a guide that a person, perhaps himself, regards as overriding and wants adopted by everyone else, or (2) is a universal guide that all rational persons would put forward for governing the behavior of all moral agents. When a person uses “morality” to refer to a guide to conduct put forward by a group, unless it is his own group, it is usually only being used in its descriptive sense. No one referring to morality in that sense of “morality” need be endorsing it. When “morality” refers to a guide to conduct accepted by an individual, unless that individual is himself, it is usually being used in its descriptive sense. However, if the individual is referring to his own morality, he is endorsing it. Only (2) is always the normative sense of “morality,” but a person might hold that the morality referred to in (1), (1a), or (1b) is also the morality referred to in (2).

Some philosophers have put forward a sense of morality that seems to be a simple variation of (1b). In this sense, morality is a guide that a person, perhaps himself, regards as overriding, but need not want adopted by everyone else. In this technical philosophical sense of “morality,” “ethical egoism,” the view that one ought to take as one’s own self-interest as the overriding guide to behavior, is a morality. Sidgwick regarded egoism as one of the methods of ethics and, following Plato and Aristotle, “ethics” is sometimes taken as referring to a guide to behavior that an individual adopts as his own guide to life. However, in any normal sense of “morality,” morality cannot be a guide to behavior that a person wants others not to adopt. There is a sense of “morality” such that it does refer to a code of conduct adopted by an individual for his own use, but which he does not claim should be adopted by anyone else. However, this is correctly referred to as “morality” only when the individual would be willing for everyone else to adopt that code of conduct, but does not require that they do so, nor does he judge them to be immoral if they do not adopt it.

2. Normative Definitions of “morality”

When “morality” is used in its universal normative sense, it need not have either of the two features that are essential to moralities referred to by the original descriptive sense: that it be a code of conduct that is put forward by a society and that it be used as a guide to behavior by the members of that society. Indeed, it is possible that “morality” in the normative sense has never been put forward by any particular society, by any group at all, or even by any individual who regards it as overriding. “morality” is thus an ambiguous term, the features that account for what it refers to in any of the descriptive senses are not the features that account for what it refers to in its normative sense. The only feature that the descriptive and normative senses of “morality” have in common is that they refer to guides to behavior.

Those people who claim that there is a universal morality claim that it is a code of conduct that all rational persons would put forward for governing the behavior of all moral agents. They need not hold that every society has a code of conduct that has those features that they claim morality must have. They can admit that the guides to behavior of some societies lack so many of the essential features of morality that these societies do not even have a morality. They can also admit that many, perhaps most, societies have defective moralities, that although their guides to behavior have enough of the features of morality to be classified as moralities, they also lacks some essential features. Although those who hold that morality is universal do not claim that any actual society has or has ever had a guide to conduct that has all of the essential features of morality, they do not deny it either. They do claim that it is possible for any normal adult in any society to know what kinds of actions morality prohibits, requires, discourages, encourages, and allows. They also claim that morality applies to all of these persons, not only those now living, but also those who lived in the past. These are not empirical claims about morality, they are claims about what is essential to morality, or about what is meant by “morality” when it is used normatively.

On all accounts of morality, it is a code of conduct. However, on ethical or group relativist accounts or on individualistic accounts, morality has no special content or features that distinguishes it from nonmoral codes of conduct, such as law or religion. Just as a legal code of conduct can have almost any content, as long as it is capable of guiding behavior, and a religious code of conduct has no limits on content, all of the relativist and individualist accounts of morality, have no limit on the content of a moral code. However, for those, such as Hobbes, Kant, and Mill, who hold that morality is a code of conduct that all rational persons would put forward for governing the behavior of all moral agents, it has a fairly definite content. Although Kant, in accordance with the German word used to translate the English word “morality,” regards morality as applying to behavior that affects no one but the agent, he recognizes that it is commonly related to behavior that affects other people. Hobbes, Bentham, Mill, and most other philosophers writing in English limit morality to behavior that, directly or indirectly, affect others.

Although there are other significant differences between those philosophers who use “morality” to refer to a universal guide that all rational persons would put forward for governing the behavior of all moral agents, there are significant similarities. For all of these philosophers, such as Kurt Baier, Phillipa Foot, and Geoffrey Warnock, morality prohibits actions such as killing, causing pain, deceiving, and breaking

promises. For some, morality also requires charitable actions, but it does not require a justification for not being charitable on every possible occasion in the same way that it requires a justification for any act of killing, causing pain, deceiving, and breaking promises. For others, morality only encourages charitable actions, and no justification is ever needed for not being charitable. Rather, being charitable is supererogatory: it is always morally good to be charitable, but it is not morally required to be charitable.

On all of the accounts of morality as a universal guide that all rational persons would put forward for governing the behavior of all moral agents, it is concerned with promoting people living together in peace and harmony, not causing harm to others, and helping them. For most philosophers, the prohibitions against causing harm, directly or indirectly, are not taken as absolute. However, unlike most kinds of actions, a justification is needed for violating the prohibitions in order to avoid acting immorally. Some philosophers who hold a strict deontology, such as Kant, hold that it is never justified to do some of these kinds of actions. Those who hold that the principle of utility provides the foundation of morality, such as Mill, hold that it is justified to violate moral rules only when the overall direct and indirect consequences would be better. However, all those who use morality in its normative sense agree that the kinds of actions that directly or indirectly harm other people are the kinds of action with which morality is concerned.

The Natural Law tradition, from the Greeks to the present day, explicitly holds that all rational persons know what kinds of actions morality prohibits, requires, discourages, encourages, and allows. They also hold that reason endorses acting morally. Some hold that it is irrational to act immorally, but all hold that it is never irrational to act morally. Even religious thinkers in this tradition, such as Aquinas, hold that morality is known to all those whose behavior is subject to moral judgment, whether or not they know of the revelations of Christianity. Hobbes, who is in the natural law tradition, accepts all of the standard moral virtues, but complains that “the writers of moral philosophy, though they acknowledge the same virtues and vices, yet not seeing wherein consisted their goodness, nor that they come to be praised as the means of peaceable, sociable, comfortable living, place them in the mediocrity of the passions.” (*Leviathan*, Chapter 15, paragraph 40) The differences between those philosophers who hold that there is a universal morality is primarily about the foundation of morality, not about its content.

Neither Kant nor Mill regarded themselves as inventing or creating a new morality. Rather both of them, like Hobbes, regarded themselves as providing a justification for the morality that is accepted by all. Mill explicitly says:

> The intuitive, no less than what may be termed the inductive school of ethics, insists on the necessity of general laws. They both accept that the morality of an individual action is not a question of direct perception, but of the application of a law to an individual case. They recognize also, to a great extent, the same moral laws; but differ as to their evidence, and the source from which they derive their authority. (*Utilitarianism*, Chapter 1, paragraph 3)

According to Mill, Utilitarianism provides the foundation for morality. It explains and justifies the moral rules that are accepted by all. Kant also regards himself as performing the same task, explaining and

justifying a universal moral consciousness.

Some contemporary consequentialists claim that morality requires doing that act that would result in the best overall consequences. Others claim that morality requires following that rule that would result in the best overall consequences if everyone followed or accepted it. Since different consequentialists differ in their views about what consequences count as best, consequentialism does not provide a guide to conduct such that everyone knows what kinds of actions morality prohibits, requires, discourages, encourages, and allows. Of course, consequentialists think that there is a correct answer to the question about what counts as the best consequences, but they may not realize the importance of the fact that until that correct answer is found no one knows the kinds of actions morality prohibits, requires, discourages, encourages, and allows. Most consequentialists also hold that morality is universal, that it applies to all normal adult human beings. However, since not all normal adult human beings agree on what counts as the best consequences, morality no longer has an essential feature, namely, that all those who are subject to moral judgment know what kinds of actions morality prohibits, requires, discourages, encourages, and allows. Some consequentialists are not concerned with this normative sense of “morality,” but only with that guide to conduct that results in the best overall consequences. Others claim that morality does not have as an essential feature that all those subject to it know all of the kinds of actions it prohibits, etc. For them it is sufficient for morality to be that guide to behavior that leads to the best overall consequences.

In trying to provide a definition of the traditional normative sense of “morality,” I find it useful to regard morality as a public system. I use the phrase, “public system” to refer to a guide to conduct such that (1) all persons to whom it applies, all those whose behavior is to be guided and judged by that system, know what behavior the system prohibits, requires, discourages, encourages, and allows; and (2) it is not irrational for any of these persons to accept being guided and judged by that system. The paradigm examples of public systems are card games such as bridge or poker, or athletic games such as baseball, football, and basketball. Although a game is a public system, it applies only to those playing the game. Although, occasionally, someone may participate in a game without knowing its point or all of the rules that apply to those playing the game, the standard case is that all do know the point of the game as well as all of the relevant rules. If a person does not care enough about the game to abide by the rules, she can usually quit. Morality is the one public system that no rational person can quit. This is the point that Kant, without completely realizing it, captured by saying that morality is categorical. Morality applies to people simply by virtue of their being rational persons.

Since the normative sense of “morality” refers to a universal guide to behavior that all rational persons would put forward for governing the behavior of all moral agents, it is important to provide at least a brief account of what is meant by “rational person.” In this context, “rational person” is synonymous with “moral agent” and refers to those persons to whom morality applies. This includes all normal adults with sufficient knowledge and intelligence to understand what kinds of actions morality prohibits, requires, discourages, encourages, and allows, and with sufficient volitional ability to use morality as a guide for their behavior. Such persons must also seek to avoid any harm to themselves unless they believe that their action will result in someone, themselves or others, avoiding a comparable harm, or gaining a compensating good. People lacking these characteristics are not subject to moral judgment. If they lack them only temporarily, they might be excused from moral judgments in those cases.

The following definition of morality incorporates all of the essential features of morality as a guide to behavior that all rational persons would put forward for governing the behavior of all moral agents. *Morality is an informal public system applying to all rational persons, governing behavior thataffects others, and has the lessening of evil or harm as its goal*. In order to show that this definition incorporates all of the essential features of morality, I shall explain how the various parts of the definition incorporate these features.

To say that morality is a public system incorporates the essential feature that everyone who is subject to moral judgment knows what kinds of actions it prohibits, requires, discourages, encourages, and allows. It also guarantees that it is never irrational to act morally. That morality applies to all rational persons makes clear that the sense of "morality" being defined is that guide to conduct that applies to all rational persons. It would take considerably more space than is appropriate here to show that defining morality as a public system that applies to all rational persons also results in morality being a universal guide to behavior that all rational persons would put forward for governing the behavior of all moral agents. I should make clear that the claim that all rational persons would put forward this system only follows if limitations are put on the beliefs that rational persons can use and if they are attempting to reach agreement with similarly limited rational persons.

To say that morality is an informal system means that it has no authoritative judges and no decision procedure that provides unique answers to all moral questions. When it is important that disagreements be settled, societies use political and legal systems to supplement morality. These formal systems have the means to provide unique answers, but they do not provide a moral answer to the question. Rather, the question, being regarded as morally unresolvable, is transferred to the political or legal system. An important example of such a moral question is whether, and if so under what conditions, to allow abortion. There is continuing disagreement about this moral question, even though the legal and political system in the United States has provided fairly clear guidelines about the conditions under which abortion is allowed. Despite this important and controversial issue, morality, like all informal public systems, presupposes overwhelming agreement on most moral questions. No one thinks it is morally justified to cheat, deceive, injure, or kill simply in order to gain sufficient money to take a fantastic vacation. In the vast majority of moral situations, given agreement on the facts, no one disagrees, but for this very reason, these situations are never discussed. Thus, the overwhelming agreement on most moral matters is often overlooked.

The claim that morality governs behavior that affects others is somewhat controversial. Some have claimed that morality governs behavior that affects only the agent herself. Examples of behavior that supposedly affects only oneself, often include taking recreational drugs, masturbation, and developing one's talents. The German word for morality does include behavior that affects only the agent herself, and Kant may provide an accurate account of the German concept of morality. This concept of morality is more closely tied to its religious origin. However, the English concept of morality is more completely secular and almost all who distinguish morality from religion regard morality as governing only that behavior that directly or indirectly affects others. It is likely that regarding self-affecting behavior as governed by morality is a holdover from the time when morality was not clearly distinguished from

religion. This religious holdover might also affect the claim that some sexual practices such as homosexuality are immoral, but those who distinguish morality from religion do not regard homosexuality, per se, as a moral matter. Almost all American colleges and universities prohibit discrimination against homosexuals, which strongly suggests that they agree that only behavior that adversely affects others counts as immoral.

The final characteristic of morality -- that it has the lessening of evil or harm as its goal -- is also somewhat controversial. The Utilitarians talk about producing the greatest good as the goal of morality. However they include the lessening of harm as essential to producing the greatest good and almost all of their examples involve the avoiding or preventing of harm. The paradigm cases of moral precepts involve rules which prohibit causing harm directly or indirectly, such as rules prohibiting killing, causing pain, deceiving, and breaking promises. Even those precepts that require or encourage positive action, such as helping the needy, are almost always related to preventing or relieving harms. An examination of the paradigm examples of moral precepts make it clear that all of them involve the lessening of harms. It would be possible to include these paradigm examples of moral precepts in the definition of morality. This addition would make explicit that the normative sense of “morality” refers to that guide to behavior that we all regard as morality, but it not necessary to do so, because the proposed definition is sufficient to guarantee that these paradigm moral precepts will be part of the moral system.

Dictionary definitions of referring terms are usually just descriptions of the essential features of the referents of those terms. Insofar as all the referents of a term share the features that account for why that term refers to those referents, the term is not regarded as ambiguous. “morality” is an ambiguous term. Unlike the descriptive definitions of morality discussed earlier, which do not have any implications about how a person should behave, this normative definition of morality does have such implications. Hence it is not surprising that it is controversial. Agreeing to this definition commits a person to regarding some behavior as immoral, perhaps even behavior that he is tempted to perform. Although this definition allows as meaningful the question, “Why should I be moral?”, it guarantees that there is an answer that shows that it is not irrational to be moral, even though it may not show that it is irrational to be immoral. This definition also explains why we want others to act morally and why others want us to act morally. It thus does what definitions of referring terms are supposed to do: it clarifies this term's relationship to other terms with which it is related, and explains why we use the word in the way that we do.

Hobbes’s Moral and Political Philosophy

The 17th Century English philosopher Thomas Hobbes is now widely regarded as one of a handful of truly great political philosophers, whose masterwork *Leviathan* rivals in significance the political writings of Plato, Aristotle, Locke, Rousseau, Kant, and Rawls. Hobbes is famous for his early and elaborate development of what has come to be known as “social contract theory”, the method of justifying political principles or arrangements by appeal to the agreement that would be made among suitably situated rational, free, and equal persons. He is infamous for having used the social contract method to arrive at the astonishing conclusion that we ought to submit to the authority of an absolute -- undivided and unlimited -- sovereign power. While his methodological innovation had a profound constructive impact on subsequent work in political philosophy, his substantive conclusions have served mostly as a foil for the development of more palatable philosophical positions. Hobbes’s moral philosophy has been less influential than his political philosophy, in part because that theory is too ambiguous to have garnered any general consensus as to its content. Most scholars have taken Hobbes to have affirmed some sort of personal relativism or subjectivism; but views that Hobbes espoused divine command theory, virtue ethics, rule egoism, or a form of projectivism also find support in Hobbes’s texts and among scholars. Because Hobbes held that “the true doctrine of the Lawes of Nature is the true Morall philosophie”, differences in interpretation of Hobbes’s moral philosophy can be traced to differing understandings of the status and operation of Hobbes’s “laws of nature”, which laws will be discussed below. The formerly dominant view that Hobbes espoused psychological egoism as the foundation of his moral theory is currently widely rejected, and there has been to date no fully systematic study of Hobbes’s moral psychology.

---

1. Major Political Writings

Hobbes wrote several versions of his political philosophy, including *The Elements of Law, Natural and Politic* (also under the titles *Human Nature* and *De Corpore Politico)* published in 1650, *De Cive* (1642) published in English as *Philosophical Rudiments Concerning Government and Society* in 1651, the English *Leviathan* published in 1651, and its Latin revision in 1668. Others of his works are also important in understanding his political philosophy, especially his history of the English Civil War, *Behemoth* (published 1679), *De Corpore* (1655), *De Homine* (1658), *Dialogue Between a Philosopher and a Student of the Common Laws of England* (1681), and *The Questions Concerning Liberty, Necessity, and Chance* (1656). All of Hobbes's major writings are collected in *The English Works of Thomas Hobbes*, edited by Sir William Molesworth (11 volumes, London 1839-45), and *Thomae Hobbesƒ Opera Philosophica Quae Latina Scripsit Omnia*, also edited by Molesworth (5 volumes; London, 1839-45). Readers new to Hobbes should begin with *Leviathan*, being sure to read Parts Three and Four, as well as the more familiar and often excerpted Parts One and Two. There are many fine overviews of Hobbes's normative philosophy, some of which are listed in the following selected bibliography of secondary works.

2. The Philosophical Project

Hobbes sought to discover rational principles for the construction of a civil polity that would not be subject to destruction from within. Having lived through the period of political disintegration culminating in the English Civil War, he came to the view that the burdens of even the most oppressive government are "scarce sensible, in respect of the miseries, and horrible calamities, that accompany a Civill Warre". Because virtually any government would be better than a civil war, and, according to Hobbes's analysis, all but absolute governments are systematically prone to dissolution into civil war, people ought to submit themselves to an absolute political authority. Continued stability will require that they also refrain from the sorts of actions that might undermine such a regime. In particular, Hobbes aimed to demonstrate the reciprocal relationship between political obedience and peace.

3. The State of Nature

To establish these conclusions, Hobbes invites us to consider what life would be like in a state of nature, that is, a condition without government. Perhaps we would imagine that people might fare best in such a state, where each decides for himself how to act, and is judge, jury and executioner in his own case whenever disputes arise-- and that at any rate, this state is the appropriate baseline against which to judge the justifiability of political arrangements. Hobbes terms this situation "the condition of mere nature", a

state of perfectly private judgment, in which there is no agency with recognized authority to arbitrate disputes and effective power to enforce its decisions.

Hobbes’s near descendant, John Locke, insisted in his *Second Treatise of Government* that the state of nature was indeed to be preferred to subjection to the arbitrary power of an absolute sovereign. But Hobbes famously argued that such a “dissolute condition of masterlesse men, without subjection to Lawes, and a coercive Power to tye their hands from rapine, and revenge” would make impossible all of the basic security upon which comfortable, sociable, civilized life depends. There would be “no place for industry, because the fruit thereof is uncertain; and consequently no culture of the earth; no navigation, nor use of the commodities that may be imported by Sea; no commodious Building; no Instruments of moving and removing such things as require much force; no Knowledge of the face of the Earth; no account of Time; no Arts; no Letters; and which is worst of all, continuall feare, and danger of violent death; And the life of man, solitary, poore, nasty, brutish, and short.” If this is the state of nature, men have strong reasons to avoid it, which can be done only by submitting to some mutually recognized public authority, for “so long a man is in the condition of mere nature, (which is a condition of war,) as private appetite is the measure of good and evill.”

Although many readers have criticized Hobbes’s state of nature as unduly pessimistic, he constructs it from a number of individually plausible empirical and normative assumptions. He assumes that people are sufficiently similar in their mental and physical attributes that no one is invulnerable nor can expect to be able to dominate the others. Hobbes assumes that people generally “shun death”, and that the desire to preserve their own lives is very strong in most people. While people have local affections, their benevolence is limited, and they have a tendency to partiality. Concerned that others should agree with their own high opinions of themselves, people are sensitive to slights. They make evaluative judgments, but often use seemingly impersonal terms like ‘good’ and ‘bad’ to stand for their own personal preferences. They are curious about the causes of events, and anxious about their futures; according to Hobbes, these characteristics incline people to adopt religious beliefs, although the content of those beliefs will differ depending upon the sort of religious education one has happened to receive.

With respect to normative assumptions, Hobbes ascribes to each person in the state of nature a liberty right to preserve herself, which he terms “the right of nature”. This is the right to do whatever one sincerely judges needful for one’s preservation; yet because it is at least possible that virtually anything might be judged necessary for one’s preservation, this theoretically limited right of nature becomes in practice an unlimited right to potentially anything, or, as Hobbes puts it, a right “to all things”. Hobbes further assumes as a principle of practical rationality, that people should adopt what they see to be the necessary means to their most important ends.

4. The State of Nature is a State of War

Taken together, these plausible descriptive and normative assumptions yield a state of nature potentially fraught with divisive struggle. The right of each to all things invites serious conflict, especially if there is competition for resources, as there will surely be over at least scarce goods such as the most desirable

lands, spouses, etc. People will quite naturally fear that others may (citing the right of nature) invade them, and may rationally plan to strike first as an anticipatory defense. Moreover, that minority of prideful or “vain-glorious” persons who take pleasure in exercising power over others will naturally illicit preemptive defensive responses from others. Conflict will be further fueled by disagreement in religious views, in moral judgments, and over matters as mundane as what goods one actually needs, and what respect one properly merits. Hobbes imagines a state of nature in which each person is free to decide for himself what he needs, what he’s owed, what’s respectful, right, pious, prudent, and also free to decide all of these questions for the behavior of everyone else as well, and to act on his judgments as he thinks best, enforcing his views where he can. In this situation where there is no common authority to resolve these many and serious disputes, we can easily imagine with Hobbes that the state of nature would become a “state of war”, even worse, a war of “all against all”.

5. Further Questions about the State of Nature

In response to the natural question whether humanity ever was generally in any such state of nature, Hobbes notes that all sovereigns are in this state with respect to one another. He opined that many now civilized peoples were formerly in that state, and some few peoples -- the savages of 17th C. America, for instance -- were still to his day in the state of nature. Most significantly, Hobbes asserts that the state of nature will be easily recognized by those whose formerly peaceful states have collapsed into civil war. While the state of nature’s condition of perfectly private judgment is an abstraction, something resembling it too closely for comfort remains a perpetually present possibility, to be feared, and avoided.

Do the other assumptions of Hobbes’s philosophy license the existence of this imagined state of isolated individuals pursuing their private judgments? Probably not, since, as feminist critics among others have noted, children are by Hobbes’s theory assumed to have undertaken an obligation of obedience to their parents in exchange for nurturing, and so the primitive units in the state of nature will include families ordered by internal obligations, as well as individuals. The bonds of affection, sexual affinity, and friendship -- as well as of clan membership and shared religious belief -- may further decrease the accuracy of any purely individualistic model of the state of nature. This concession need not impugn Hobbes’s analysis of conflict in the state of nature, since it may turn out that competition, diffidence and glory-seeking are disastrous sources of conflicts among small groups just as much as they are among individuals. Still, commentators seeking to answer the question how precisely we should understand Hobbes’s state of nature are investigating the degree to which Hobbes imagines that to be a condition of interaction among isolated individuals.

Another important open question is that of what, exactly, it is about human beings that makes it the case (supposing Hobbes is right) that our communal life is prone to disaster when we are left to interact according only to our own individual judgments. Perhaps, while people do wish to act for their own best long-term interest, they are shortsighted, and so indulge their current interests without properly considering the effects of their current behavior on their long-term interest. This would be a type of failure of rationality. Alternative, it may be that people in the state of nature are fully rational, but are trapped in a situation that makes it individually rational for each to act in a way that is sub-optimal for

all, perhaps finding themselves in the familiar ‘prisoner’s dilemma’ of game theory. Or again, it may be that Hobbes’s state of nature would be peaceful but for the presence of persons (just a few, or perhaps all, to some degree) whose passions overrule their calmer judgments; who are prideful, spiteful, partial, envious, jealous, and in other ways prone to behave in ways that lead to war. Such an account would understand irrational human passions to be the source of conflict. Which, if any, of these accounts adequately answers to Hobbes’s text is a matter of continuing debate among Hobbes scholars.

6. The Laws of Nature

Hobbes argues that the state of nature is a miserable state of war in which none of our important human ends are reliably realizable. Happily, human nature also provides resources to escape this miserable condition. Hobbes argues that each of us, as a rational being, can see that a war of all against all is inimical to the satisfaction of her interests, and so can agree that “peace is good, and therefore also the way or means of peace ƒ are good”. Humans will recognize as imperatives the injunction to seek peace, and to do those things necessary to secure it, when they can do so safely. Hobbes calls these practical imperatives “Lawes of Nature”, the sum of which is not to treat others in ways we would not have them treat us. These “precepts”, “conclusions” or “theorems” of reason are “eternal and immutable”, always commanding our assent even when they may not safely be acted upon. They forbid many familiar vices such as iniquity, cruelty, and ingratitude. Although commentators do not agree on whether these laws should be regarded as mere precepts of prudence, or rather as divine commands, or moral imperatives of some other sort, all agree that Hobbes understands them to direct people to submit to political authority. They tell us to seek peace with willing others by laying down part of our “right to all things”, by mutually covenanting to submit to the authority of a sovereign, and further direct us to keep that covenant establishing sovereignty.

7. Establishing Sovereign Authority

When people mutually covenant each to the others to obey a common authority, they have established what Hobbes calls “sovereignty by institution”. When, threatened by a conqueror, they covenant for protection by promising obedience, they have established “sovereignty by acquisition”. These are equally legitimate ways of establishing sovereignty, according to Hobbes, and their underlying motivation is the same-- namely fear-- whether of one’s fellows or of a conqueror. Political legitimacy depends not on how a government came to power, but only on whether it can effectively protect those who have consented to obey it; political obligation ends when protection ceases.

8. Absolutism

Although Hobbes offered some mild pragmatic grounds for preferring monarchy to other forms of government, his main concern was to argue that effective government -- whatever its form -- must have absolute authority. Its powers must be neither divided nor limited. The powers of legislation,

adjudication, enforcement, taxation, war-making (and the less familiar right of control of normative doctrine) are connected in such a way that a loss of one may thwart effective exercise of the rest; for example, legislation without interpretation and enforcement will not serve to regulate conduct. Only a government that possesses all of what Hobbes terms the “essential rights of sovereignty” can be reliably effective, since where partial sets of these rights are held by different bodies that disagree in their judgments as to what is to be done, paralysis of effective government, or degeneration into a civil war to settle their dispute, may occur.

Similarly, to impose limitation on the authority of the government is to invite irresoluble disputes over whether it has overstepped those limits. If each person is to decide for herself whether the government should be obeyed, factional disagreement -- and war to settle the issue, or at least paralysis of effective government -- are quite possible. To refer resolution of the question to some further authority, itself also limited and so open to challenge for overstepping its bounds, would be to initiate an infinite regress of non-authoritative ‘authorities’ (where the buck never stops). To refer it to a further authority itself unlimited, would be just to relocate the seat of absolute sovereignty, a position entirely consistent with Hobbes’s insistence on absolutism. To avoid the horrible prospect of governmental collapse and return to the state of nature, people should treat their sovereign as having absolute authority.

9. The Limits of Political Obligation

While Hobbes insists that we should regard our governments as having absolute authority, he reserves to subjects the liberty of disobeying those of their government’s commands that would require them to sacrifice their lives or honor, at least when the commonwealth’s survival does not depend on their doing so. This exception has understandably intrigued those who study Hobbes. His ascription of apparently inalienable rights -- what he calls the “true liberties of subjects” -- seems incompatible with his defense of absolute sovereignty. Moreover, if the sovereign’s failure to provide adequate protection to subjects extinguishes their obligation to obey, and if it is left to each subject to judge for herself the adequacy of that protection, it seems that people have never really exited the fearsome state of nature.

10. Religion and Social Instability

The last crucial aspect of Hobbes’s political philosophy is his treatment of religion. Hobbes progressively expands his discussion of Christian religion in each revision of his political philosophy, until it comes in *Leviathan* to comprise roughly half the book. There is no settled consensus on how Hobbes understands the significance of religion within his political theory. Some commentators have argued that Hobbes is trying to demonstrate to his readers the compatibility of his political theory with core Christian commitments, since it may seem that Christians’ religious duties forbid their affording the sort of absolute obedience to their governors which Hobbes’s theory requires of them. Others have doubted the sincerity of his professed Christianity, arguing that by the use of irony or other subtle rhetorical devices, Hobbes sought to undermine his readers’ religious beliefs. Howsoever his intentions are properly understood, Hobbes’s obvious concern with the power of religious belief is a fact that interpreters of his

political philosophy must seek to explain.

Selected Bibliography

The secondary literature on Hobbes's moral and political philosophy (not to speak of his entire body of work) is vast, appearing across many disciplines and in many languages. The following is a narrow selection of fairly recent works by philosophers, political theorists, and intellectual historians, available in English, on main areas of inquiry in Hobbes's moral and political thought. Very helpful for further reference is the critical bibliography of Hobbes scholarship to 1990 contained in Perez Zagorin, 'Hobbes on Our Mind', *Journal of the History of Ideas*, vol. 51, no. 2 (1990).

Journals

- *Hobbes Studies* is an annually published journal devoted to scholarly research on all aspects of Hobbes's work.

Contractarianism

"Contractarianism" names both a political theory of the legitimacy of political authority and a moral theory about the origin and/or legitimate content of moral norms. The political theory of authority claims that legitimate authority of government must derive from the consent of the governed, where the form and content of this consent derives from the idea of contract or mutual agreement. The moral theory of contractarianism claims that moral norms derive their normative force from the idea of contract or mutual agreement. Contractarians are thus skeptical of the possibility of grounding morality or political authority in either divine will or some perfectionist ideal of the nature of humanity. Social contract theorists from the history of political thought include Hobbes, Locke, Kant, and Rousseau. The most important contemporary political social contract theorist is John Rawls, who effectively resurrected social contract theory in the second half of the 20th century, along with David Gauthier, who is primarily a moral contractarian. There is no necessity for a contractarian about political theory to be a contractarian about moral theory, although most contemporary contractarians are both. It has been more recently recognized that there are two distinct strains of social contract thought, which now typically go by the names "contractarianism"and "contractualism."

Contractarianism, which stems from the Hobbesian line of social contract thought, holds that persons are primarily self-interested, and that a rational assessment of the best strategy for attaining the maximization of their self-interest will lead them to act morally (where the moral norms are determined by the maximization of joint interest) and to consent to governmental authority. Contractualism, which stems from the Kantian line of social contract thought, holds that rationality requires that we respect persons, which in turn requires that moral principles be such that they can be justified to each person. Thus, individuals are not taken to be motivated by self-interest but rather by a commitment to publicly justify the standards of morality to which each will be held. Where Gauthier or economist James Buchanan are the paradigm Hobbesian contractarians, Rawls or Thomas Scanlon would be the paradigm Kantian contractualists. The rest of this entry will specifically pertain to the contractarian strain wherever the two diverge.

Fundamental Elements of Contractarianism

The social contract has two fundamental elements: a characterization of the initial situation, called variously the "state of nature" by the modern political philosophers, the "original position" by Rawls, or the "initial bargaining position" by Gauthier, and a characterization of the parties to the contract, particularly in terms of their rationality and motivation to come to agreement. The initial situation posits what in bargaining theory is called the "no agreement position," the situation to which the individuals return in case of failure to make an agreement or contract. This situation may be more or less hostile, and more or less social, depending on what the theorist sees as human nature in the absence of rules of justice. But crucial to all contractarian theories, there is some scarcity or motivation for competition in the initial situation and there is some potential for gains from social interaction and cooperation.

In contemporary normative contractarian theories, that is, theories that attempt to ground the legitimacy of government or theories that claim to derive a moral ought, the initial position represents the starting point for a fair, impartial agreement. While contractualists justify the requirement of a fair, impartial agreement by reasons external to the contract itself, contractarians hold that the success of the contract in securing cooperative interaction itself requires that the starting point and procedures be fair and impartial.

Some points of controversy among contractarians concern the role of the initial situation in the theory: is it to be considered an actual historical situation, a possible historical moment, or is the contract situation completely hypothetical? Hume ("Of the Original Contract," pp.470-1) raised the decisive objection to any normative moral or political theory based on a historical contract: the consent of one's ancestors do not bind oneself. But Ronald Dworkin has raised similar concerns about a hypothetical contract: a hypothetical agreement, he objects, is no agreement at all. Hypothetical contract contractarians such as Gauthier counter that the point of the contract device is not to directly bind the contractors, but rather to provide a kind of thought experiment by which to discover the requirements of practical rationality. That is, they argue that if one is rational, and among rational others in circumstances in which agreement is both possible and beneficial, then rationality requires that one abide by the terms of the contract. While mainstream contractarian theories are hypothetical contract theories, a recent interesting and powerfully subversive use of contractarianism (Mills,1997; Pateman, 1989 -- see section on Subversion of Contractarianism below) reads the contract situation as historical agreements to erect and maintain white supremacy and patriarchy or male dominance. These latter contractarian theories are not justifications of the status quo, of course, but rather condemnations, and therefore do not face Hume's objection. Other questions that divide contemporary contractarians include: What are the ideal conditions and who are the ideal contractors that will make obligatory the outcomes of the contract for actual persons? What is the content of the hypothetical agreement?

The second element of a contractarian theory is the rationality of the contractors. First, contractarian (as opposed to contractualist) theories usually take persons to be self-interested in order to justify rules of morality or justice. This is because persons are assumed to have given preferences and interests, that do not necessarily include the well being of others, which is taken to be a moral preference and as such not prior to morality. Such preferences are called (by Gauthier, following the economist Wicksteed) "non-tuistic" preferences. Secondly, persons are presumed to want the benefits of social interaction if they can be had without sacrifice of individual self-interest. (See Feminist Perspectives on the Self (Section 1. Critique) for a critique of this conception of the rational person.) These two aspects of the contractarian individual in part imply what Rawls called the "circumstances of justice": the conditions under which rules for justice could be both possible and necessary. Justice, and so a social contract, is only possible where there is some possibility of benefit to each individual from cooperation. Social contract theories take individuals to be the best judges of their interests and the means to satisfy their desires. For this reason, there is a close connection between liberalism and contractarianism. However, that is not to say that all contractarian thought is liberal. Hobbes, for example, argued in favor of what Jean Hampton has called the "alienation contract," that is, a contract on the part of a people to alienate their rights to adjudicate their own disputes and self-defense to a sovereign, on the grounds that that was the only way to keep the peace given the nature of the alternative, which he famously characterized as life that would be "solitary, poore, nasty, brutish, and short." Thus, given a bad enough initial situation, contractarianism may lead to the legitimation of totalitarianism. Another point of criticism that arises from the characterization of the parties to the contract is that they must be able to contribute to the social product of interaction, or at least to threaten to destabilize it. This is because each individual has to be able to benefit from the inclusion of all those included. But this obviously leaves many, such as the severely disabled(though not the more able disabled -- see Silvers, 1998), outside the realm of justice, an implication that some find completely unacceptable. (Kittay, 1999)

Social contract theories also require some rules to guide the formation of agreement. Since they are prior to the contract, there must be some source of prior moral norms, whether natural, rational, or conventional. The first rule that is normally prescribed is that there must be no force or fraud in the making of the agreement. No one is to be "coerced" into agreement by the threat of physical violence. The reasoning for this is quite straightforwardly prudential: if one is allowed to use violence, then there is no real difference between the "contract" arrived at and the state of nature for the threatened party, and hence no security in the agreement. However, there is a fine line between being coerced by the threat of violence to giving up one's rights and being convinced by the threat of penury to make an unfavorable agreement. For this reason contractarians like Gauthier are able to argue for a fair and impartial starting point for bargaining that will lead to secure and stable agreements. The second rule of contract is that each individual who is a legitimate party to the contract must agree to the rules of justice, which is the outcome of the contract.

The Metaphor of Contract

The metaphor of the social contract requires some interpretation in order to apply it to the situation of

morality or politics. The interpretation can be specified by determining answers to three questions. First, what is the agreement on? Possible answers include the principles of justice (Rousseau, Rawls), the design of the basic social institutions (Rawls), the commitment to give up to a sovereign government (some or all of) one's rights (Hobbes, Locke), the adoption of a disposition to be (conventionally) moral (Gauthier, Hampton). The second question is how the agreement is to be thought of: as a hypothetical agreement? An actual historical agreement? An implicit historical situation? The third question is whether the contract device is to be used as justification or explanation. As discussed above, normative contractarianism uses the contract device primarily as justification, but it may be that Hobbes and Locke thought that there was an explanatory element to the contract device. As will be discussed below (Subversions of Contractarianism), an important contemporary contractarianism uses an implicit contract to explain the origin of oppression.

Morals by Agreement -- David Gauthier's Contractarianism

A brief sketch of an influential contractarian theory, David Gauthier's, is in order. Gauthier's project in *Morals By Agreement* is to employ a contractarian approach to grounding morality in rationality in order to defeat the moral skeptic. Gauthier assumes that humans can have no natural harmony of interests, and that there is much for each individual to be gained through cooperation. According to Gauthier, moral constraint on the pursuit of individual self-interest is required because cooperative activities almost inevitably involve a prisoner's dilemma: a situation in which the best individual outcomes can be had by those who cheat on the agreement while the others keep their part of the bargain. This leads to the socially and individually sub-optimal outcome wherein each can expect to be cheated by the other. But by disposing themselves to act according to the requirements of morality whenever others are also so disposed, they can gain each others' trust and cooperate successfully.

The contractarian element of the theory comes in the derivation of the moral norms. According to Gauthier, the compliance problem -- the problem of justifying rational compliance with the norms that have been accepted -- must always drive the justification of the initial situation and the conduct of the contracting situation. Gauthier likens the contract situation to a bargain, in which each party is trying to negotiate the moral rules that will allow them to realize optimal utility, and then he argues in favor of a bargaining solution that he calls "maximin relative concession." The idea of maximin relative concession is that each bargainer will be most concerned with the concessions that she makes from her ideal outcome relative to the concessions that others make. If she sees her concessions as reasonable relative to the others, considering that she wants to ensure as much for herself as she can while securing agreement (and thereby avoiding the zero-point: no share of the cooperative surplus) and subsequent compliance from the others, then she will agree to it. What would then be the reasonable outcome? Gauthier argues that it is the outcome that minimizes the maximum relative concessions of each party to the bargain.

Equally important to the solution as the procedure is the starting point from which the parties begin. For Gauthier there is no veil of ignorance -- each party to the contract is fully informed of their personal

attributes and holdings. But Gauthier argues that the initial position must have been arrived at non-coercively if compliance to the agreement is to be secured. He thus adopts what he calls the "Lockean proviso" (modeled after Locke's description of the initial situation of his social contract): that one cannot have bettered himself by worsening others. In sum, the moral norms that rational contractors will adopt (and comply with), according to Gauthier, are those norms that would be reached by the contractors beginning from a position each has attained through her own actions which have not worsened anyone else, and adopting as their principle for agreement the rule of maximin relative concession.

Critiques of Normative Contractarianism

Many critiques have been leveled against particular contractarian theories and against contractarianism as a framework for normative thought about justice or morality. (See Contemporary Approaches to the Social Contract.) Jean Hampton criticized Hobbes in her book *Hobbes and the Social Contract Tradition*, in a way that has direct relevance to contemporary contractarianism. Hampton argues that the characterization of individuals in the state of nature leads to a dilemma. Hobbes' state of nature as a potential war of all against all can be generated either as a result of passions (greed and fear, in particular) or rationality (prisoner's dilemma reasoning, in which the rational players each choose to renege on agreements made with each other). But if the passions account is correct, then Hampton argues, the contractors will still be motivated by these passions after the social contract is drawn up, and so will fail to comply with it. And if the rationality account is correct, then rational actors will not comply with the social contract any more than they will cooperate with each other before it is made.

This critique has an analog for Gauthier's theory, in that Gauthier must also claim that without the contract individuals will be stuck in some socially sub-optimal situation that is bad enough to motivate them to make concessions to each other for some agreement, yet the reason for their inability to cooperate without the contract cannot continue to operate after the contract is made. Gauthier's proposed solution to this problem is to argue that individuals will choose to dispose themselves to be constrained (self-interest) maximizers rather than straightforward (self-interest) maximizers, that is, to retrain themselves not to think first of their self-interest, but rather to dispose themselves to keep their agreements, provided that they find themselves in an environment of like-minded individuals. But this solution has been found dubitable by many commentators. (See Vallentyne, 1991)

Hampton also objects to the contemporary contractarian assumption that interaction is merely instrumentally valuable. She argues that if interaction were only valuable for the fruits of cooperation that it bears for self-interested cooperators, then it would be unlikely that those cooperators could successfully solve the compliance problem. In short, they are likely not to be able to motivate morality in themselves without some natural inclination to morality. Interestingly, Hampton agrees with Gauthier that contractarianism is right to require any moral or political norms to appeal to individuals self-interest as a limitation on self-sacrifice or exploitation of any individual.

In an important article, "On Being the Object of Property," African-American law professor Patricia Williams offers a critique of the contract metaphor itself. Contracts require independent agents who are

able to make and carry out promises without the aid of others. Historically, while white men have been treated as these pure wills of contract theory, Blacks and women have been treated as anti-will: dependent and irrational. Both ideals are false; whole people, she says, are dependent on other whole people. But by defining some as contractors and others as incapable of contract, whole classes of people can be excluded from the realm of justice. This point has been taken up by other critics of contractarianism, such as Eva Kittay (1999) who points out that not only are dependents such as children and disabled people left out of consideration by contractarian theories, but their caretakers' needs and interests will tend to be underestimated in the contract, as well.

Subversive Contractarianism

A descriptive use to which contractarianism has recently been put is to exploit the in-group/out-group nature of the contractarian project to illuminate the phenomenon of oppression. Carole Pateman's The Sexual Contract (1989) uses contractarian theory to argue that there has been an implicit contract among men to enforce patriarchy. She calls her approach a "conjectural history," which she uses both to illuminate the actual history of patriarchal oppression of women and the ideology of social contract theory. Similarly, Charles Mills argues in *The Racial Contract* (1997) that whites have had an actual, historical, sometimes explicit, though often only implicit, contract to enforce white supremacy. The arguments are similar in their contractarian outlines, though they differ in the historical and factual details. According to both theories, there are moral, political, and epistemological terms of the contract, and its effect has been to allow one group of persons effectively to dominate, subordinate, and exploit another group. The moral terms require the dominant group to evaluate the lives of their group more highly than those of the subordinated, the political to deprive the subordinate group of effective political power, and the epistemological terms require the members of the dominant group to see themselves as intellectually superior to the dominated. The social contract then can be seen as a justification by the parties to the contract of their interaction, and of their exploitation of those who are not parties to the contract, but only if the fundamental division of in-group and out-group is accepted. If the racial and sexual contracts were to be shown to be rational, they would constitute prima facie critiques of normative contractarianism, since they would then seem to justify racism and sexism.

Several of the critiques surveyed above, then, center on the questions: who is allowed to be a party to the contract, and how are those who are excluded from the contract to be treated? On the normative contractarian view, it is only rational to include all of those who can both benefit and reciprocate benefits to others. Normative contractarianism, then, on the assumption that non-whites and women can both benefit and reciprocate benefits to others, shows the sexual and racial contracts to be fundamentally irrational. Disability rights activists, however, would still have a serious complaint to lodge against normative contractarianism, since it is surely the case that there are persons who cannot reciprocate benefits to others. Such persons would be, on the normative contractarian view, beyond the scope of the rules of justice.

Moral Dilemmas

Moral dilemmas, at the very least, involve conflicts between moral requirements. Consider the cases given below.

1. Examples

In Book I of Plato's *Republic*, Cephalus defines 'justice' as speaking the truth and paying one's debts. Socrates quickly refutes this account by suggesting that it would be wrong to repay certain debts -- for example, to return a borrowed weapon to a friend who is not in his right mind. Socrates' point is not that repaying debts is without moral import; rather, he wants to show that it is not always right to repay one's debts, at least not exactly when the one to whom the debt is owed demands repayment. What we have here is a conflict between two moral norms: repaying one's debts and protecting others from harm. And in this case, Socrates maintains that protecting others from harm is the norm that takes priority.

Nearly twenty-four centuries later, Jean-Paul Sartre described a moral conflict the resolution of which was, to many, less obvious than the resolution to the Platonic conflict. Sartre [1957] tells of a student whose brother had been killed in the German offensive of 1940. The student wanted to avenge his brother and to fight forces that he regarded as evil. But the student's mother was living with him, and he was her one consolation in life. The student believed that he had conflicting obligations. Sartre describes him as

being torn between two kinds of morality: one of limited scope but certain efficacy, personal devotion to his mother; the other of much wider scope but uncertain efficacy, attempting to contribute to the defeat of an unjust aggressor.

While the examples from Plato and Sartre are the ones most commonly cited, it should be clear that there are many others. If a person makes conflicting promises, she faces a moral conflict. Physicians and families who believe that human life should not be shortened and that unpreventable pain should not be tolerated face a conflict in deciding whether to withdraw life support from a dying patient.

2. The Concept of Moral Dilemmas

What is common to the two well-known cases is conflict. In each case, an agent regards herself as having moral reasons to do each of two actions, but doing both actions is not possible. Ethicists have called situations like these *moral dilemmas*. The crucial features of a moral dilemma are these: the agent is required to do each of two (or more) actions; the agent can do each of the actions; but the agent cannot do both (or all) of the actions. The agent thus seems condemned to moral failure; no matter what she does, she will do something wrong (or fail to do something that she ought to do).

The Platonic case strikes many as too easy to be characterized as a genuine moral dilemma. For the agent's solution in that case is clear; it is more important to protect people from harm than to return a borrowed weapon. And in any case, the borrowed item can be returned later, when the owner no longer poses a threat to others. Thus in this case we can say that the requirement to protect others from serious harm *overrides* the requirement to repay one's debts by returning a borrowed item when its owner so demands. When one of the conflicting requirements overrides the other, we do not have a genuine moral dilemma. So in addition to the features mentioned above, in order to have a *genuine* moral dilemma it must also be true that neither of the conflicting requirements is overridden [Sinnott-Armstrong (1988), Chapter 1].

3. Problems

It is less obvious in Sartre's case that one of the requirements overrides the other. Why this is so, however, may not be so obvious. Some will say that our uncertainty about what to do in this case is simply the result of uncertainty about the consequences. If we were certain that the student could make a difference in defeating the Germans, the obligation to join the military would prevail. But if the student made little difference whatsoever in that cause, then his obligation to tend to his mother's needs would take precedence, since there he is virtually certain to be helpful. Others, though, will say that these obligations are equally weighty, and that uncertainty about the consequences is not at issue here.

Ethicists as diverse as Kant [1971/1797], Mill [1979/1861], and Ross [1930 and 1939] have assumed that an adequate moral theory should not allow for the possibility of genuine moral dilemmas. Only recently -- in the last forty years or so -- have philosophers begun to challenge that assumption. And the challenge

can take at least two different forms. Some will argue that it is *not possible* to preclude genuine moral dilemmas. Others will argue that even if it were possible, it is *not desirable* to do so.

To illustrate some of the debate that occurs regarding whether it is possible for any theory to eliminate genuine moral dilemmas, consider the following. The conflicts in Plato's case and in Sartre's case arose because there is more than one moral precept (using 'precept' to designate rules and principles), more than one precept sometimes applies to the same situation, and in some of these cases the precepts demand conflicting actions. One obvious solution here would be to arrange the precepts, however many there might be, hierarchically. By this scheme, the highest ordered precept always prevails, the second prevails unless it conflicts with the first, and so on. There are at least two glaring problems with this obvious solution, however. First, it just does not seem credible to hold that moral rules and principles should be hierarchically ordered. While the requirements to keep one's promises and to prevent harm to others clearly can conflict, it is far from clear that one of these requirements should *always* prevail over the other. In the Platonic case, the obligation to prevent harm is clearly stronger. But there can easily be cases where the harm that can be prevented is relatively mild and the promise that is to be kept is very important. And most other pairs of precepts are like this. This was a point made by Ross in *The Right and the Good* [1930, Chapter 2].

The second problem with this easy solution is deeper. Even if it were plausible to arrange moral precepts hierarchically, situations can arise in which the same precept gives rise to conflicting obligations. Perhaps the most widely discussed case of this sort is taken from William Styron's *Sophie's Choice* [1980] [Greenspan (1983)]. Sophie and her two children are at a Nazi concentration camp. A guard confronts Sophie and tells her that one of her children will be allowed to live and one will be killed. But it is Sophie who must decide which child will be killed. Sophie can prevent the death of either of her children, but only by condemning the other to be killed. The guard makes the situation even more excruciating by informing Sophie that if she chooses neither, then both will be killed. With this added factor, Sophie has a morally compelling reason to choose one of her children. But for each child, Sophie has an apparently equally strong reason to save him or her. Thus the same moral precept gives rise to conflicting obligations. Some have called such cases *symmetrical* [Sinnott-Armstrong (1988), Chapter 2].

4. Dilemmas and Consistency

We shall return to the issue of whether it is possible to preclude genuine moral dilemmas. But what about the desirability of doing so? Why have ethicists thought that their theories should preclude the possibility of dilemmas? At the intuitive level, the existence of moral dilemmas suggests some sort of inconsistency. An agent caught in a genuine dilemma is required to do each of two acts but cannot do both. And since he cannot do both, not doing one is a condition of doing the other. Thus, it seems that the same act is both required and forbidden. But exposing a logical inconsistency takes some work; for initial inspection reveals that the inconsistency intuitively felt is not present. Allowing *OA* to designate that the agent in question ought to do *A* (or is morally obligated to do *A*, or is morally required to do *A*), that *OA* and *OB* are both true is not itself inconsistent, even if one adds that it is not possible for the agent to do both *A* and *B*. And even if the situation is appropriately described as OA and O¬A, that is not a contradiction; the

contradictory of OA is ¬OA. [See Marcus (1980).]

Similarly rules that generate moral dilemmas are not inconsistent, at least on the usual understanding of that term. Ruth Marcus suggests plausibly that we “define a set of rules as consistent if there is some possible world in which they are all obeyable in all circumstances in *that* world.” Thus, “rules are consistent if there are possible circumstances in which no conflict will emerge,” and “a set of rules is inconsistent if there are *no* circumstances, no possible world, in which all the rules are satisfiable” [Marcus (1980), p. 128 and p. 129]. I suspect that Kant, Mill, and Ross were aware that a dilemma-generating theory need not be inconsistent. Even so, they would be disturbed if their own theories allowed for such predicaments. If I am correct in this speculation, it suggests that Kant, Mill, Ross, and others thought that there is an important theoretical feature that dilemma-generating theories lack. And this is understandable. It is certainly no comfort to an agent facing a reputed moral dilemma to be told that at least the rules which generate this predicament are consistent. For a good practical example, consider the situation of the criminal defense attorney. She is said to have an obligation to hold in confidence the disclosures made by a client and to be required to conduct herself with candor before the court (where the latter requires that the attorney inform the court when her client commits perjury) [Freedman (1975), Chapter 3]. It is clear that in this world these two obligations often conflict. It is equally clear that in some possible world -- for example, one in which clients do not commit perjury -- that both obligations can be satisfied. Knowing this is of no assistance to defense attorneys who face a conflict between these two requirements in this world.

Ethicists who are concerned that their theories not allow for moral dilemmas have more than consistency in mind, I think. What is troubling is that theories that allow for dilemmas fail to be *uniquely action-guiding*. A theory can fail to be uniquely action-guiding in either of two ways: by not recommending any action in a situation that is moral or by recommending incompatible actions. Theories that generate genuine moral dilemmas fail to be uniquely action-guiding in the latter way. Since at least one of the main points of moral theories is to provide agents with guidance, that suggests that it is desirable for theories to eliminate dilemmas, at least if doing so is possible.

But failing to be uniquely action-guiding is not the only reason that the existence of moral dilemmas is thought to be troublesome. Just as important, the existence of dilemmas does lead to inconsistencies if one endorses certain widely held theses. Here we shall consider two different arguments, each of which shows that one cannot consistently acknowledge the reality of moral dilemmas while holding selected principles.

The first argument shows that two standard principles of deontic logic are, when conjoined, incompatible with the existence of moral dilemmas. The first of these is the principle of deontic consistency

> **Principle of Deontic Consistency** (**PC**):
> $OA \rightarrow \neg O \neg A$.

Intuitively this principle just says that the same action cannot be both obligatory and forbidden. Note that as initially described, the existence of dilemmas does not conflict with PC. For as described, dilemmas

involve a situation in which an agent ought to do *A*, ought to do *B*, but cannot do both *A* and *B*. But if we add a principle of deontic logic, then we obtain a conflict with PC:

Principle of Deontic Logic (**PD**):
$\Box (A \rightarrow B) \rightarrow (OA \rightarrow OB)$.

Intuitively, PD just says that if doing *A* brings about *B*, and if *A* is obligatory (morally required), then *B* is obligatory (morally required). The *first argument* that generates inconsistency can now be stated.

(1)	OA	
(2)	OB	
(3)	¬ C (A & B)	[where '¬C' means 'cannot']
(4)	$\Box$ (A → B) → (OA → OB)	[where '$\Box$' means physical necessity]
(5)	$\Box$ ¬ (B & A)	(from 3)
(6)	$\Box$ (B → ¬ A)	(from 5)
(7)	$\Box$ (B → ¬ A) → (OB → O¬ A)	(an instantiation of 4)
(8)	OB → O¬ A	(from 6 and 7)
(9)	O¬ A	(from 2 and 8)
(10)	OA and O¬ A	(from 1 and 9)

Line (10) directly conflicts with PC. And from PC and (1), we can conclude

(11) ¬ O¬ A

And, of course, (9) and (11) are contradictory. So if we assume PC and PD, then the existence of dilemmas generates an inconsistency of the old-fashioned logical sort. [Note: In standard deontic logic, the '$\Box$' in PD typically designates logical necessity. Here I take it to indicate physical necessity so that the appropriate connection with premise (3) can be made. And I take it that logical necessity is stronger than physical necessity.]

Two other principles accepted in most systems of deontic logic entail PC. So if PD holds, then one of these additional two principles must be jettisoned too. The first says that if an action is obligatory, it is also permissible. The second says that an action is permissible if and only if it is not forbidden. These principles may be stated as:

(OP): OA → PA;

and

(D): $PA \leftrightarrow \neg O \neg A$.

The *second argument* that generates inconsistency, like the first, has as its first three premises a symbolic representation of a moral dilemma.

(1) OA
(2) OB
(3) $\neg C (A \& B)$

And like the first, this second argument shows that the existence of dilemmas leads to a contradiction if we assume two other commonly accepted principles. The first of these principles is that ‘ought’ implies ‘can’. Intuitively this says that if an agent is morally required to do an action, it must be possible for the agent to do it. We may represent this as

(4) $OA \rightarrow CA$ (for all A)

The other principle, endorsed by most systems of deontic logic, says that if an agent is required to do each of two actions, she is required to do both. We may represent this as

(5) $(OA \& OB) \rightarrow O(A \& B)$

The argument then proceeds:

(6) $O(A \& B) \rightarrow C(A \& B)$	(an instance of 4)
(7) $OA \& OB$	(from 1 and 2)
(8) $O(A \& B)$	(from 5 and 7)
(9) $\neg O(A \& B)$	(from 3 and 6)

So if one assumes that ‘ought’ implies ‘can’ and if one assumes the principle represented in (5) -- dubbed by some the agglomeration principle [Williams (1965)] -- then again a contradiction can be derived.

5. Responses to the Arguments

Now obviously the inconsistency in the first argument can be avoided if one denies either PC or PD. And the inconsistency in the second argument can be averted if one gives up either the principle that ‘ought’ implies ‘can’ or the agglomeration principle. There is, of course, another way to avoid these inconsistencies: deny the possibility of genuine moral dilemmas. It is fair to say that much of the debate concerning moral dilemmas in the last forty years has been about how to avoid the inconsistencies generated by the two arguments above.

Opponents of moral dilemmas have generally held that the crucial principles in the two arguments above are conceptually true, and therefore we must deny the possibility of genuine dilemmas. [See, for example, Conee (1982) and Zimmerman (1996).] Most of the debate, from all sides, has focused on the second argument. There is an oddity about this, however. When one examines the pertinent principles in each argument which, in combination with dilemmas, generates an inconsistency, there is little doubt that those in the first argument have a greater claim to being conceptually true than those in the second. Perhaps the focus on the second argument is due to the impact of Bernard Williams's influential essay [Williams (1965)]. But notice that the first argument shows that if there are genuine dilemmas, then either PC or PD must be relinquished. Even most supporters of dilemmas acknowledge that PC is quite basic. E.J. Lemmon, for example, notes that if PC does not hold in a system of deontic logic, then all that remains are truisms and paradoxes [Lemmon (1965), p. 51]. And giving up PC also requires denying either OP or D, each of which also seems basic. There has been much debate about PD -- in particular, questions generated by the Good Samaritan paradox -- but still it seems basic. So those who want to argue against dilemmas purely on conceptual grounds are better off focusing on the first of the two arguments above.

Some opponents of dilemmas also hold that the pertinent principles in the second argument -- the principle that 'ought' implies 'can' and the agglomeration principle -- are conceptually true. But foes of dilemmas need not say this. Even if they believe that a conceptual argument against dilemmas can be made by appealing to PC and PD, they have several options regarding the second argument. They may defend 'ought' implies 'can', but hold that it is a substantive normative principle, not a conceptual truth. Or they may even deny the truth of 'ought' implies 'can' or the agglomeration principle, though not because of moral dilemmas, of course.

Defenders of dilemmas need not deny all of the pertinent principles, of course. If one thinks that each of the principles at least has some initial plausibility, then one will be inclined to retain as many as possible. Among the earlier contributors to this debate, some took the existence of dilemmas as a counterexample to 'ought' implies 'can' [for example, Lemmon (1962) and Trigg (1971)]; others, as a refutation of the agglomeration principle [for example, Williams (1965) and van Fraassen (1973)]. The most common response to the first argument was to deny PD.

Friends and foes of dilemmas have a burden to bear in responding to the two arguments above. For there is at a *prima facie* plausibility to the claim that there are moral dilemmas and to the claim that the relevant principles in the two arguments are true. Thus each side must at least give reasons for denying the pertinent claims in question. Opponents of dilemmas must say something in response to the positive arguments that are given for the reality of such conflicts. One reason, as noted above, is simply pointing to examples. The case of Sartre's student and that from *Sophie's Choice* are good ones; and clearly these can be multiplied indefinitely. It will tempting for supporters of dilemmas to say to opponents, "If this is not a real dilemma, then tell me *what* the agent ought to do and *why*?" It is obvious, however, that attempting to answer such questions is fruitless, and for at least two reasons. First, any answer given to the question is likely to be controversial, certainly not always convincing. And second, this is a game that will never end; example after example can be produced. The more appropriate response on the part of foes of dilemmas is to deny that they need to answer the question. Examples as such cannot establish the

reality of dilemmas. Surely most will acknowledge that there are situations in which an agent does not know what he ought to do. This may be because of factual uncertainty, uncertainty about the consequences, uncertainty about what principles apply, or a host of other things. So for any given case, the mere fact that one does not know which of two (or more) conflicting obligations prevails does not show that none does.

Another reason in support of dilemmas to which opponents must respond is the point about symmetry. As the cases from Plato and Sartre show, moral rules can conflict. But opponents of dilemmas can argue that in such cases one rule overrides the other. Most will grant this in the Platonic case, and opponents of dilemmas will try to extend this point to all cases. But the hardest case for opponents is the symmetrical one, where the same precept generates the conflicting requirements. The case from *Sophie's Choice* is of this sort. It makes no sense to say that a rule or principle overrides itself. So what do opponents of dilemmas say here? They are apt to argue that the pertinent, all-things-considered requirement in such a case is disjunctive: Sophie should act to save one or the other of her children, since that is the best that she can do [for example, Zimmerman (1996), Chapter 7]. Such a move need not be *ad hoc*, since in many cases it is quite natural. If an agent can afford to make a meaningful contribution to only one charity, the fact that there are several worthwhile candidates does not prompt many to say that the agent will fail morally no matter what he does. Nearly all of us think that he should give to one or the other of the worthy candidates. Similarly, if two people are drowning and an agent is situated so that she can save either of the two but only one, few say that she is doing wrong no matter which she saves. Positing a disjunctive requirement in these cases seems perfectly natural, and so such a move is available to opponents of dilemmas as a response to symmetrical cases.

Supporters of dilemmas have a burden to bear too. They need to cast doubt on the adequacy of the pertinent principles in the two arguments that generate inconsistencies. And most importantly, they need to provide independent reasons for doubting whichever of the principles they reject. If they have no reason other than cases of putative dilemmas for denying the principles in question, then we have a mere standoff. Of the principles in question, the most commonly questioned on independent grounds are the principle that 'ought' implies 'can' and PD. Among supporters of dilemmas, Walter Sinnott-Armstrong [Sinnott-Armstrong (1988), Chapters 4 and 5] has gone to the greatest lengths to provide independent reasons for questioning some of the relevant principles.

6. Moral Residue and Dilemmas

One well-known argument for the reality of moral dilemmas has not been discussed yet. This argument might be called "phenomenological." It appeals to the emotions that agents facing conflicts experience and our assessment of those emotions.

Return to the case of Sartre's student. Suppose that he joins the Free French forces. It is likely that he will experience remorse or guilt for having abandoned his mother. And not only will he experience these emotions, this moral residue, but it is appropriate that he does. Yet, had he stayed with his mother and not joined the Free French forces, he also would have appropriately experienced remorse or guilt. But

remorse or guilt are appropriate only if the agent properly believes that he has done something wrong (or failed to do something that he was all-things-considered required to do). Since no matter what the agent does he will appropriately experience remorse or guilt, then no matter what he does he will have done something wrong. Thus, the agent faces a genuine moral dilemma. [The best known proponents of arguments for dilemmas that appeal to moral residue are Williams (1965) and Marcus (1980).]

Many cases of moral conflict are similar to this example. Certainly the case from *Sophie's Choice* fits here. No matter which of her children Sophie saves, she will experience enormous guilt for the consequences of that choice. Indeed, if Sophie did not experience such guilt, we would think that there was something morally wrong with her. In these cases, proponents of the argument (for dilemmas) from moral residue must claim that four things are true: (1) when the agents acts, she experiences remorse or guilt; (2) that she experiences these emotions is appropriate and called for; (3) had the agent acted on the other of the conflicting requirements, she would also have experienced remorse or guilt; and (4) in the latter case these emotions would have been equally appropriate and called for [McConnell (1996), pp. 37-38]. In these situations, then, remorse or guilt will be appropriate no matter what the agent does and these emotions are appropriate only when the agent has done something wrong. Therefore, these situations are genuinely dilemmatic.

There is much to say about the moral emotions and situations of moral conflict; the positions are varied and intricate. Without pretending to resolve all of the issues here, it will be pointed out that opponents of dilemmas have raised two different objections to the argument from moral residue. The first objection, in effect, suggests that the argument is question-begging [McConnell (1978) and Conee (1982)]; the second objection challenges the assumption that remorse and guilt are appropriate only when the agent has done wrong.

To explain the first objection, note that it is uncontroversial that some bad feeling or other is called for when an agent is in a situation like that of Sartre's student or Sophie. But the negative moral emotions are not limited to remorse and guilt. Among these other emotions, consider regret. An agent can appropriately experience regret even when she does not believe that she has done something wrong. For example, a parent may appropriately regret that she must punish her child even though she correctly believes that the punishment is deserved. Her regret is appropriate because a bad state of affairs is brought into existence (say, the child's discomfort), even when bringing this state of affairs into existence is morally required. Regret can even be appropriate when one has no causal connection at all with the bad state of affairs. It is appropriate for me to regret the damage that a recent fire has caused to my neighbor's house, the pain that severe birth defects cause in infants, and the suffering that a starving animal experiences in the wilderness. Not only is it appropriate that I experience regret in these cases, but I would probably be regarded as morally lacking if I did not.

With remorse or guilt, at least two components are present: the *experiential* component, namely, the negative feeling that the agent has; and the *cognitive* component, namely, the belief that the agent has done something wrong and takes responsibility for it. Although this same cognitive component is not part of regret, the negative feeling is. And the experiential component alone cannot serve as a gauge to distinguish regret from remorse, for regret can range from mild to intense, and so can remorse. In part,

what distinguishes the two is the cognitive component. But now when we examine the case of an alleged dilemma, such as that of Sartre's student, it is question-begging to assert that it is appropriate for him to experience remorse no matter what he does. No doubt, it is appropriate for him to experience *some* negative feeling. To say, however, that it is remorse that is called for is to assume that the agent appropriately believes that he has done something wrong. Since regret is warranted even in the absence of such a belief, to assume that remorse is appropriate is to *assume*, not argue, that the agent's situation is genuinely dilemmatic. Opponents of dilemmas can say that one of the requirements overrides the other, or that the agent faces a disjunctive requirement, and that regret is appropriate because even when he does what he ought to do, some bad will ensue. Either side, then, can account for the appropriateness of some negative moral emotion. To get more specific, however, requires more than is warranted by the present argument. This appeal to moral residue, then, does not establish the reality of moral dilemmas.

Matters are even more complicated, though, as the second objection to the argument from moral residue shows. The argument assumes that remorse or guilt is appropriate only if the agent believes that he has done something wrong. But this is questionable. Consider the case of a middle-aged man, Bill, and a seven-year-old boy, Johnny. It is set in a midwestern village on a snowy December day. Johnny and several of his friends are riding their sleds down a narrow, seldom used street, one that intersects with a busier, although still not heavily traveled, street. Johnny, in his enthusiasm for sledding, is not being very careful. During his final ride he skidded under an automobile passing through the intersection and was killed instantly. The car was driven by Bill. Bill was driving safely, had the right of way, and was not exceeding the speed limit. Moreover, given the physical arrangement, it would have been impossible for Bill to have seen Johnny coming. Bill was not at fault, legally or morally, for Johnny's death. Yet Bill experienced what can only be described as remorse or guilt about his role in this horrible event.

At one level, Bill's feelings of remorse or guilt are not warranted. Bill did nothing wrong. A friend might even recommend that Bill seek therapy. But this is not all there is to say. Most of us understand Bill's response. From Bill's point of view, the response is not inappropriate, not irrational, not uncalled-for. To see this, imagine that Bill had had a very different response. Suppose that Bill had said, "I regret Johnny's death. It is a terrible thing. But it certainly was not my fault. I have nothing to feel guilty about and I don't owe his parents any apologies." Even if Bill is correct intellectually, it is hard to imagine someone being able to achieve this sort of objectivity about his own behavior. When human beings have caused great harm, it is natural for them to wonder if they are at fault, even if to outsiders it is obvious that they bear no moral responsibility for the damage. Human beings are not so finely tuned emotionally that when they have been *causally* responsible for harm, they can easily turn guilt on or off depending on their degree of *moral* responsibility. [See Zimmerman (1988), pp. 134-135.] And this is not a bad thing; for it likely makes agents more cautious about their actions, more sensitive about their responsibilities, and more empathetic regarding the plight of others.

All of this suggests that there are situations in which an agent's remorse or guilt is not inappropriate even though the agent has done nothing wrong. Because of this and because in any given situation the appropriate response may be regret and not remorse, opponents of dilemmas have a way to respond to the argument that appeals to the appropriateness of remorse.

It should be noted, however, that there is a complex array of issues concerning the relationship between ethical conflicts and the moral emotions, and the discussion here has been quite brief. [See Greenspan (1995).]

7. Types of Moral Dilemmas

In the literature on moral dilemmas, it is common to draw distinctions among various types of dilemmas. Only some of these distinctions will be mentioned here. It is worth noting that both supporters and opponents of dilemmas tend to draw some, if not all, of these distinctions. And in most cases the motivation for doing so is clear. Supporters of dilemmas may draw a distinction between dilemmas of type V and W. The upshot is typically a message to opponents of dilemmas: "You think that all moral conflicts are resolvable. And that is understandable, because conflicts of type V are resolvable. But conflicts of type W are not resolvable. Thus, contrary to your view, there are some genuine moral dilemmas." By the same token, opponents of dilemmas may draw a distinction between dilemmas of type X and Y. And their message to supporters of dilemmas is this: "You think that there are genuine moral dilemmas, and given certain facts, it is understandable why this appears to be the case. But if you draw a distinction between conflicts of types X and Y, you can see that appearances can be explained by the existence of type X alone, and type X conflicts are not genuine dilemmas." With this in mind, let us note a few of the distinctions.

One distinction is between *epistemic* conflicts and *ontological* conflicts. The former involve conflicts between two (or more) moral requirements and the agent does not know which of the conflicting requirements takes precedence in her situation. Everyone concedes that there can be situations where one requirement does take priority over the other with which it conflicts, though at the time action is called for it is difficult for the agent to tell which requirement prevails. The latter are conflicts between two (or more) moral requirements, and neither is overridden. This is not simply because the agent does not *know* which requirement is stronger; neither is. Genuine moral dilemmas, if there are any, are ontological. Both opponents and supporters of dilemmas acknowledge that there are epistemic conflicts.

Another distinction is between *self-imposed* moral dilemmas and dilemmas imposed on an agent *by the world*, as it were. Conflicts of the former sort arise because of the agent's own wrongdoing [Aquinas; Donagan (1977 and 1984); and McConnell (1978)]. If an agent made two promises that he knew conflicted, then through his own actions he created a situation in which it is not possible for him to discharge both of his requirements. Dilemmas imposed on the agent by the world, by contrast, do not arise because of the agent's wrongdoing. The case of Sartre's student is an example, as is the case from *Sophie's Choice*. For supporters of dilemmas, this distinction is not all that important. But among opponents of dilemmas, there is a disagreement about whether the distinction is important. Some of these opponents hold that self-imposed dilemmas are possible, but that their existence does not point to any deep flaws in moral theory. Moral theory tells agents how they ought to behave; but if agents violate moral norms, of course things can go askew. Other opponents deny that even self-imposed dilemmas are possible. They argue that an adequate moral theory should tell agents what they ought to do in their current circumstances, regardless of how those circumstances arose. And given the prevalence of

wrongdoing, if a moral theory did not issue uniquely action-guiding "contrary-to-duty imperatives," it would be severely lacking.

Yet another distinction is between *obligation dilemmas* and *prohibition dilemmas*. The former are situations in which more than one feasible action is obligatory. The latter involve cases in which all feasible actions are forbidden. Some [especially, Valentyne (1987 and 1989)] argue that plausible principles of deontic logic may well render obligation dilemmas impossible; but they do not preclude the possibility of prohibition dilemmas. The case of Sartre's student, if genuinely dilemmatic, is an obligation dilemma; Sophie's case is a prohibition dilemma. There is another reason that friends of dilemmas emphasize this distinction. Some think that the "disjunctive solution" used by opponents of dilemmas -- when equally strong precepts conflict, the agent is required to act on one or the other -- is much more plausible when applied to obligation dilemmas than when applied to prohibition dilemmas.

As moral dilemmas are typically described, they involve a *single agent*. The agent ought, all things considered, to do A, ought, all things considered, to do B, and she cannot do both A and B. But we can distinguish *multi-person* dilemmas from single agent ones. The two-person case is representative of multi-person dilemmas. The situation is such that one agent, P1, ought to do A, a second agent, P2, ought to do B, and though each agent can do what he ought to do, it is not possible both for P1 to do A and P2 to do B. [See Marcus (1980), p. 122 and McConnell (1988).] Multi-person dilemmas have been called "interpersonal moral conflicts." Such conflicts are most theoretically worrisome if the same moral system (or theory) generates the conflicting obligations for P1 and P2. A theory that precludes single-agent moral dilemmas remains uniquely action-guiding for each agent. But if that same theory does not preclude the possibility of interpersonal moral conflicts, not all agents will be able to succeed in discharging their obligations, no matter how well-motivated or how hard they try. For supporters of moral dilemmas, this distinction is not all that important. They no doubt welcome (theoretically) more types of dilemmas, since that may make their case more persuasive. But if they establish the reality of single-agent dilemmas, in one sense their work is done. For opponents of dilemmas, however, the distinction may be important. This is because at least some opponents believe that the conceptual argument against dilemmas applies principally to single-agent cases. It does so because the ought-to-do operator of deontic logic and the accompanying principles are properly understood to apply to entities about which decisions can be made. And while an individual act involving one agent can be the object of choice, a compound act involving multiple agents is difficult so to conceive. [See Smith (1986) and Thomason (1981).] To the extent that the possibility of interpersonal moral conflicts raises an intramural dispute among opponents of dilemmas, that dispute concerns how to understand the principles of deontic logic and what can reasonably be demanded of moral theories.

8. Conclusion

Debates about moral dilemmas have been extensive during the last four decades. These debates go to the heart of moral theory. Both supporters and opponents of moral dilemmas have major burdens to bear. Opponents of dilemmas must show why appearances are deceiving. Why are examples of apparent dilemmas misleading? Why are certain moral emotions appropriate if the agent has done no wrong?

Supporters must show why several of many apparently plausible principles should be given up -- principles such as PC, PD, OP, D, ‘ought’ implies ‘can’, and the agglomeration principle. Much progress has been made, but the debate is apt to continue.

Finitism in Geometry

In our representations of the world, especially in physics, infinities play a crucial role. The continuum of the real numbers as a representation of time or one-dimensional space is the best known example. However, these same infinities also cause problems. One just has to think about Zeno's paradoxes or the present-day continuation of that discussion, namely, the discussion about supertasks, to see the difficulties. Hence, it is a very tempting idea to investigate whether it is possible to eliminate these infinities and still be able to do physics. This problem reduces first of all to the question of the possibility of a discrete geometry that can approximate classical infinite geometry as closely as possible. If a positive answer can be given to this question, the second question is what could be the possible physical relevance (if any).

---

1. What is Finitism in Geometry?

1.1 Finitism in mathematics

Finitism is one of the foundational views of mathematics that is listed under the broader heading of constructivism. It shares with the many forms of constructivism the fundamental view that mathematical

objects and concepts have to be accessible to the mathematician in terms of constructions that can be executed or performed. The various forms are distinguished from one another as to how ‘execution’ or ‘performance’ is to be understood. Usually outside finitism the potentially infinite is allowed, i.e., if a procedure or algorithm will (provably) terminate at some moment in the future, then the outcome is accepted as constructable. See Bridges & Richman [1997] for an overview. However, finitism goes one step further and argues that an indefinite outcome is not be accepted as an outcome, since, as all computational resources are finite, it could very well be that these resources have been used up before the outcome has been reached.

Usually the label *strict* finitism is used to describe the view sketched above. The additional qualification serves to make the distinction with Hilbert’s finitism which, roughly speaking, can be seen as a form of finitism on the meta-level (e.g., although mathematical theories can talk about infinite structures, still the proofs in such theories must have a finite length). Here the discussion will be limited to strict finitism.

As might be expected, strict finitism is not a popular view in the philosophy of mathematics. Nevertheless a number of proposals have been put forward. A history and an account of the actual (though now somewhat dated) state of affairs can be found in Welti [1987].

1.2 The special case of geometry

It is rather striking that the various proposals that are discussed in Welti’s book focus mainly on numbers and numerals. Less attention has been paid to the problem of geometry. Nevertheless the basic premise seems easy enough to formulate, namely that a geometrical space is finitely extended and that it is composed of a finite number of geometrical basic units, that themselves are not decomposable. These basic units are sometimes called ‘(geometrical) atoms’ or ‘hodons’.

Formulated thus, the problem might seem trivial. After all, there is a separate branch of mathematics that studies finite geometries. There is however an important difference. Although such geometries can be very inspiring for a strict finitist proposal (as will be shown in section 2), their aim is not to provide an *alternative* for continuous infinite geometries. In addition for the strict finitist geometer, success or failure is not solely determined by *internal* mathematical arguments or considerations. Rather the hope is that such alternatives will prove to be relevant for applications to the sciences, the case *par excellence* being physics. If one could successfully replace the classical geometrical continuum structure of space-time by a strict finitist analogue, then, from a philosophical point of view, the consequences would be of great importance. Two obvious topics present themselves as test cases: Zeno’s paradoxes and supertasks. If space and time are discrete, then the runner, the tortoise, Achilles and all other moving objects simply go through a finite number of space locations in a finite number of time elements and all the problems with supertasks vanish as a one-minute time interval is no longer divisible in a denumerable series of intervals. These topics will not be treated here and the reader is referred to the related entries.

In the very same sense, there is a clear difference with all the theories and proposals that have been put forward in the computer sciences. The problem one faces there is precisely to set up a translation from a

classical geometrical model to a model whereof the domain (usually) consists of the finite set of pixels or cells that make up the computer screen. Although equally inspiring, the drawback here is that nearly all these models assume the classical (infinite) model in the background and, hence, do not have a proper foundation of their own (a situation quite analogous to numerical analysis that relies on classical analysis for proving the correctness of the procedures). Note also that these theories should not be confused with computer programs that have the ability to reason *about* geometrical objects. This is part of the research area of automated reasoning and its basic objects are proofs, not necessarily the mathematical objects the proofs are about.

Finally, although there have been numerous proposals for discrete worldviews throughout the history of western culture, see, e.g., White [1992], the focus here is on the twentieth-century developments.

2. A Classic Proposal for a Discrete Geometry

As most of the work that has been done has been limited to the plane, this presentation will also be restricted to that particular case (in most proposals the extension to higher dimensional geometries is considered completely straightforward). There are different routes to follow. One possibility is to take any axiomatisation of the (Euclidean) plane—say, Hilbert's formulation of 1899 in his *Grundlagen der Geometrie*—and show what changes are required to have (a) finite models of the axiomatic theory, and (b) finite models that approximate the classical (infinite, Euclidean) models as closely as possible. One of the very first attempts dates back to the late 40s, early 50s and will therefore be presented here as an exemplar (in the sense that it has both all the positive qualities required as well as the oddities that seem to go together with such attempts). More specifically, it concerns the work of Paul Kustaanheimo in partial collaboration with G. Järnefelt in the period between 1949 and 1957.

2.1 A standard axiomatisation for Euclidean plane geometry

What does a Hilbert-type axiomatisation look like? The first thing one has to do is to fix a (formal) language. Usually one chooses first-order predicate logic with identity, i.e., a language containing names for variables (and, possibly, for constants), names for functions (if necessary), names for predicates including the identity predicate, logical connectives and quantifiers, and a set of grammatical rules to form sentences. The restriction to first-order logic means that only variables can be quantified over. Without going into details, it should be remarked that a more expressive language can be chosen, e.g., whereby quantification over predicates is allowed as well.

If a language has been chosen, the next problem is to determine the primitive terms of the language. For plane Euclidean geometry, these are points and lines, although sometimes lines are defined as particular sets of points. Next the basic predicates have to be selected. There exist a number of different axiomatisations at the present moment. The most frequently used predicates are: the incidence relation ("a point *a* lies on a line *A*"), the betweenness relation ("point *a* lies between points *b* and *c*"), the equidistance relation ("the distance from point *a* to *b* is the same as the distance from point *c* to *d*"), the

congruence relation ("a part of a line, determined by two point *a* and *b* is congruent to a part of a line, determined by two points *c* and *d*"). Note that it is not necessary that all of them occur in an axiomatisation. As an example, if lines are not introduced as primitive terms, then usually there is no incidence relation.

The next step is the introduction of a set of axioms to determine certain properties of the above mentioned relations. As an example, if the axiomatisation uses the incidence relation, then the typical axioms for that relation are:

a. Through two points exactly one straight line can be drawn.
b. There are at least two points on every straight line.
c. There are at least three points that are not on the same straight line.

Finally, one looks for an interpretation or a model of the axiomatisation. This means that we search for a meaning of the primitive terms, such as points and lines, of the functions (if any) and of the predicates in such a way that the axioms become true statements relative to the interpretation. Although we often have a particular interpretation in mind when we develop an axiomatisation, it does not exclude the possibility of the existence of rather unexpected models. In a sense finitist models rely on this very possibility as the next paragraph shows.

2.2 Kustaanheimo's finitist approach

Kustaanheimo's proposal—I reproduce here in rough outline the excellent presentation of his proposal in Welti [1987], pp. 487-521, which is far more accessible than the original work—is based on the following line of reasoning. A standard model for the classical axiomatic theory of Euclidean geometry consists of the cartesian product of the real numbers with itself. Or, as it is usually formulated, a point in the plane is mapped onto a couple of real numbers, its coordinates. The real numbers have the mathematical structure of an infinite field. But finite fields exist as well. So why not replace the infinite real number field with a finite field, a so-called Galois field?

The best result one could obtain would be that every finite Galois field satisfies most of the axioms of Euclidean geometry. That however is not the case. The outcome of Kustaanheimo's research is slightly more complicated:

> (a) Not all finite fields will do. If we call *p* the number of elements in the domain of the finite field, then *p* has to satisfy some conditions. This means that only finite fields of a particular size, i.e., a specific value for *p*, are potential candidates.
>
> (b) For the "good" values of *p*, the full model will not do. As an example, take straight lines. According to their definition in a finite field, it turns out that there are two sorts of straight lines: open and closed ones. The latter ones violate some of the axioms, hence you restrict the model to the open ones. This restriction of the model is called the Euclidean

"kernel" of the model.

In short, one cannot claim that any finite field will do, but only some and for that matter only part of it.

This approach raises some important philosophical questions:

(a) It is clear that the size of the model is an important feature. Does this have any meaning? Or, negatively, what does it mean that fields of a different size are not suitable as models? Suppose as a thought experiment that Euclidean geometry is a good model for the geometrical structure of the universe. Does it make sense to claim that the universe must contain exactly p points (not p-1, not p+1)? A new sort of Pythagoreanism seems to be lurking around the corner here.

(b) The example of the straight lines shows that there are "nice" geometrical objects (those that satisfy most of the axioms) and "bad" geometrical objects. *Ignoring* the bad ones is perhaps a mathematically interesting strategy, but it does not *eliminate* them from the full model. In other words, although they do not play any relevant part in the "kernel" of the model, they are there. What is the meaning of that? To continue the above thought experiment, the question is what corresponds to the "bad" objects in the universe? If they do not correspond to anything, why do we need them in the first place to find the "good" objects?

In defense of Kustaanheimo's approach it must be said that the connections between infinite and finite models are usually far more complex than one expects. A finite model is not merely a scaled-down version of an infinite model. Very often a different structure appears. As an analogy take the (infinite set of) natural numbers. Take a finite part, say the numbers 1 up to L. In the finite case it makes sense to talk about small and large numbers compared to L. This is classically not possible. So one finds additional structure. Metaphorically speaking, by making things finite, a more detailed or "fine-grained" structure appears, that is wiped out in the presence of infinities. Perhaps the distinction between "good" and "bad" geometrical objects is such an additional feature that disappears in the classical Euclidean model. More details about Kustaanheimo's approach are to be found in the following supplementary document

Finite Fields as Models for Euclidean Plane Geometry.

The counterargument could be that one of the major disadvantages of infinite models and theories is that 'fine' details or the 'fine-grained' structure is wiped out by the infinities present, much the same as infinite numbers wipe out the distinction between small and large numbers or numerals. Thus perhaps the prime numbers do have a significance. But still the question remains: is this a new sort of Pythagoreanism?

3. Recent Proposals

In recent years some authors have focused rather on particular problems related to strict finitist geometry instead of attempting to present a full alternative. Usually the problems have been raised by those who doubt the possibility of a strict finitist position. Three problems of this sort will be discussed: the distance function problem, the dimension problem and the isotropy problem.

3.1 Three problems to deal with

The distance function problem. The argument dates back to 1949 and was first formulated by Hermann Weyl: "If a square is built up of miniature tiles, then there are as many tiles along the diagonal as there are along the sides; thus the diagonal should be equal in length to the side" (Weyl [1949], p. 43). At least two solutions to this problem have been formulated.

Van Bendegem [1987] argued that in a finite geometry it should be a basic fact that lines and points have extensions. In particular, lines are supposed to have a constant width (independent of the orientation of the line) N_D. Thus N_D represents a large (finite) number, corresponding to the number of squares that form N_D. Given a line, the width is always defined as perpendicular to that line. Now suppose that the line has an orientation corresponding to an angle α between the line and the *x*-axis. Then the width N_D of that line, when projected on the *x*-axis will be $[N_D/\sin\alpha]$ where the expression $[x]$ indicates the greatest integer less than or equal to *x*.

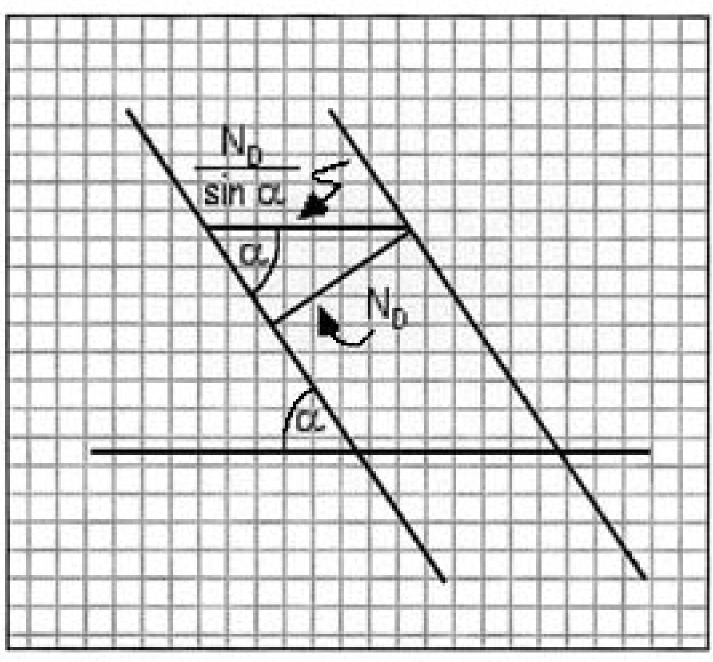

Figure 1

The distance *d* between two points *p* and *q* is then defined as the number of squares in the rectangle formed by the line from *p* to *q* and the width N_D, divided by N_D. The idea is that, although in a discrete geometry, lines must necessarily have a width, this is not an essential feature, so it can be divided out. Hence:

$d(p,q) = N_L\ .[\ N_D/\sin\ \alpha]\ (\text{div}\ N_D).$

N_L here corresponds to the number of layers parallel to the *x*-axis between *p* and *q* and *n* (div *m*) is the quotient of the division of *n* by *m*.

As an illustration, consider the Weyl problem.

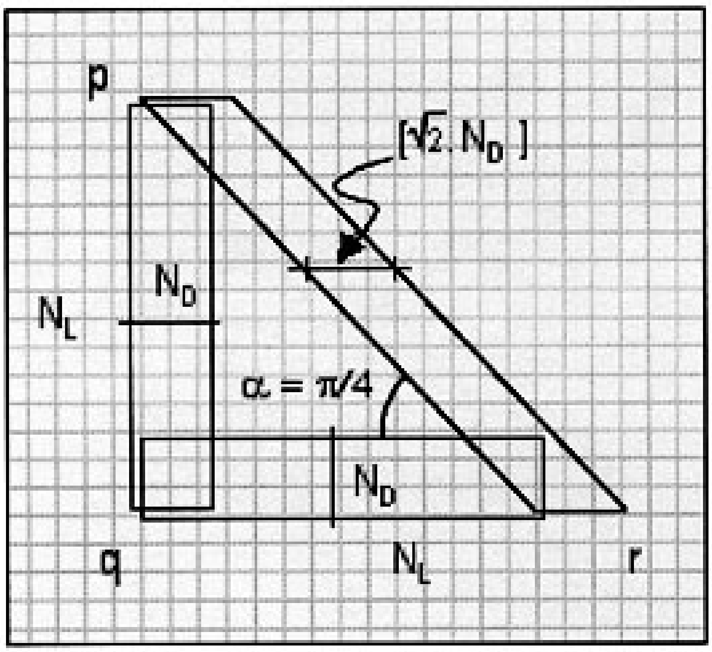

Figure 2

We have a right-angled triangle *pqr* such that for simplicity the right sides *pq* and *qr* are equal to one another and are aligned with the axes of the grid. Suppose that the number of squares in the right sides is N_L. Then

$d(p,q)= d(q,r) = N_L\ .[\ N_D]\ (\text{div}\ N_D) = N_L,$
since, of course, $[N_D] = N_D$.

However, the hypotenuse has an angle of $\alpha = \sqrt{2}/2$. Thus

$d(p,r) = N_L\ .[\ N_D/\sin\ \alpha]\ (\text{div}\ N_D)$

$= N_L.[\sqrt{2}\ .\ N_D]\ (\text{div}\ N_D)$

$= N_L.\ [\sqrt{2}]_n,$

where $[r]_n$ means the number *r* up to *n* decimals

No calculations are needed to show that the Pythagorean theorem holds, i.e., $d^2(p,q) + d^2(q,r) = d^2(p,r)$. Finally, there is an easy explanation why the Weyl problem occurs: it corresponds to the limiting case $N_D = 1$. When $N_D = 1$, then $[\sqrt{2 \cdot N_D}] = [\sqrt{2}] = 1$, hence $d(p,r) = N_L.1 = N_L$ and Pythagoras' theorem fails.

Although the introduction of a width N_D apparently solves the problem, it is equally clear what the drawbacks are. Without classical Euclidean geometry in the background, there is really no way to get the construction going. There is no definition of a line in terms of the discrete geometry, and, above all, the projected width on the *x*-axis of a line *L* is calculated according to a Euclidean distance function that is not explicitly mentioned. In short, there is a mixture of two distance functions.

Peter Forrest [1995] presents another solution. He starts by introducing a family of discrete spaces $E_{n,m}$, where *n* corresponds to the "classical" dimension of space and *m* is a scale factor, to be understood as follows: *m* is a parameter to decide when two points are or are not adjacent, which is the basic (and sole) concept of his geometry. Thus in the case $n = 2$, points are labeled by couples of integers (i, j) and two points (i, j) and (i', j') are adjacent if

a. they are distinct, and
b. $(i - i')^2 + (j - j')^2 \leq m^2$.

Once adjacency has been stipulated, a distance function can be easily derived: the distance between *p* and *q*, $d(p,q)$, is the smallest number of "links" in a chain of points connecting *p* and *q* such that each one is adjacent to the previous one. Next there is no problem to show that a straight line passing through two points is that chain of points that has the shortest distance.

If the parameter m has a small value, then the resulting distance function is not Euclidean. More specifically, if $m = 1$, then we have, once again, the situation presented by Weyl. But if, say, $m = 10^{30}$ (the figure proposed by Forrest himself), then the situation changes. Then it is possible to show that the distance function on the discrete space will approximate the Euclidean distance function as close as one wants. Without presenting all the details, one can show that a Euclidean distance function d_E and the discrete distance function *d* are related by a scale factor, i.e.,

$$d_E(p,q)/d(p, q) = \text{constant}(m),$$

where the constant is determined by the value of *m*. No calculations are needed once again, to show that the original distance function *d* satisfies the Pythagorean theorem.

If one is looking for a weak point in this approach, then inevitably one must end up with the basic notion of adjacency. What is the reason for defining adjacency in Euclidean terms? For, after all, a condition such as $(i - i')^2 + (j - j')^2 \leq m^2$ looks as Euclidean as can be.

A possible way out is suggested in Van Bendegem [1995]. One of the advantages of a discrete approach—and, as a matter of fact, this seems to hold in general for strict finitist proposals—is that definitions that are classically equivalent turn out to be distinct in a strict finitist framework. Thus, more specifically, a circle can be defined in (at least) two ways:

a. as the set of points *p* that have a fixed distance to a fixed point,
b. as the set of points *p* such that, given a fixed line segment *ab*, the angle formed by *apb* is a right angle.

Classically speaking, these two definitions are equivalent. However, they are not in a discrete geometry. If, e.g., the distance function is defined as the lowest number of hodons that connect two given points, then the two definitions are not equivalent. Using definition (a), the circle will have the shape of a square (a well-known fact in so-called taxicab geometry) and thus useless to define adjacency as done above. Definition (b) on the other hand produces a figure that can approximate a Euclidean circle as close as one likes. In that way Forrest's definition for adjacency is acceptable within a discrete framework, as no reference is made to a Euclidean distance function.

The dimension problem. Not much attention has been paid to this problem although it is fundamental. If the plane consists of a discrete set of elements, hodons or atoms, then this set must have dimension zero. For, in order to determine the dimension, this set must be equipped with a topology and the only possible candidate is the discrete topology. This entails that the dimension is zero. Either one takes the option to simply drop the notion of dimension on the basis of the argument that the concept of dimension presupposes a concept of continuity and topology and hence has no finitist meaning. Or one searches for an analog, but it is not clear at all what that could be. Something one should not try to do is to derive a notion of dimension from an ordering relation. Suppose that the hodons are labeled by integers (i, j) in some appropriate coordinate system, such that $-L \leq i, j \leq L$, where L is some upper bound. Then quite different ordering relations are possible. One possibility is to define $(i, j) < (k, l)$ if and only if $i + j < k + l$. But another possibility is to define $(i, j) < (k, l)$ if and only if either $i < k$ or, if $i = k$, then $j < l$. It therefore requires additional arguments to claim that among all possible order relations on a given set, one and only one has a special status. So far no such arguments have been produced.

The isotropy problem. If the plane is built up from square hodons, as in the paragraph above, then the hodons are arranged in such a way that every hodon touches four other hodons, i.e., the plane can be modeled as a square grid, then it is obvious that there are preferred directions, in this case, there will be two preferred directions. However if instead of squares, hexagons are taken as hodons, then there are four preferred directions. Thus no matter what the shape is of the hodon, there will be preferred directions and this implies that the space is anisotropic. However, for physical applications one would like to have isotropy (or at least as close as possible).

Two approaches are possible. Either the hodons have a definite shape or they do not. In the first case it has been suggested that instead of a regular periodic tiling of the plane, one should look for an irregular aperiodic tiling, such as the Penrose tiling.

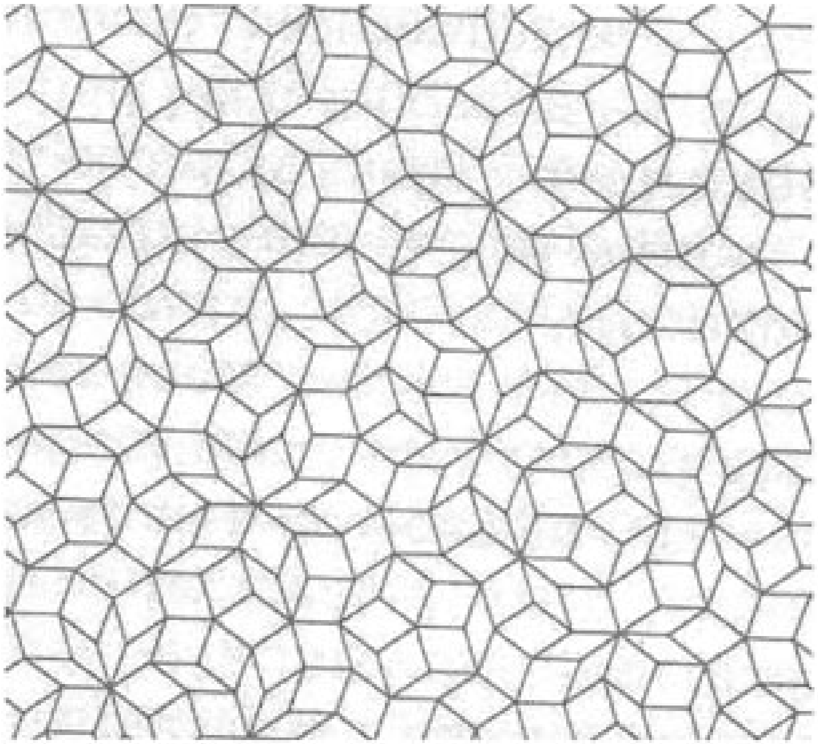

Figure 3

Although no worked-out examples are available, it seems a promising line of attack (see, e.g., Penrose Tilings and Wange Tilings, in the Other Internet Resources section), as a source of inspiration). In the case of the Penrose tiling it is interesting to see that there are no classically straight lines anymore, precisely because of the aperiodicity. In the second case vagueness is a possible way out. As Peter Forrest defends in his [1995], the whole idea of a specific representation of a discrete space, e.g., as built up from tiny squares is fundamentally mistaken. If a hodon has a specific form, then one cannot avoid asking questions about parts of a hodon, such as its border, but that does not make sense if hodons are the smallest spatial entities possible. An intermediate position defended in Van Bendegem [1995] is to consider a series of discrete geometries G_i, each with a hodon of a particular size, h_i, such that $h_i \neq h_j$, for $i \neq j$ and, in addition, there are M and N such that $M < h_i < N$, for all i. One can then apply a supervaluation technique to the series. This means that a statement will be True (False) if it is true (false) in every geometry G_i. In all other cases it is Undecided, i.e. true in some and false in some others. Now if A is the statement ‘hodons have size α’ (where α is a specific number), this will be Undecided, if a corresponds to at least one of the h_i. Such an approach however introduces all problems connected with vagueness into the discussion, which is not necessarily an encouraging situation.

3.2 The empirical question

As said in the beginning, the final test of a discrete geometry will be its application first and foremost to physics. There are basically two ways to think about such a test. Either one can think of a ‘strong’ version, viz., that is possible to design an experiment that would allow us to decide between the

continuous and the discrete case. Or one can think of a ‘weak’ version, viz., that the discrete version does at least the same things as the classical version.

In the first case the aim is to think of a crucial experiment. It is quite interesting to see that already in 1961 Paul Feyerabend suggested such a possibility. However not much more is said, as “the difficulty of the present situation seems to lie in the fact that discrete alternatives for the mathematics, which at the present moment is being used in physics, are missing” (p. 160). Equally interesting is the fact that Feyerabend too mentions the standard argument that the lack of a Pythagorean theorem is a genuine problem. His proposal is that “we need only assume that measurements in different directions do not commute; and then perhaps we can retain the theorem as an operator equation” (p. 161). Here too, unfortunately, nothing more is said. Peter Forrest [1995] maintains that such an experiment is possible. The fundamental reason is that classical mathematics uses continuous variables whereas strict finitist mathematics uses discrete variables. Thus for differentation and integration finite analogs must be found and they will approximate the classical case, but never coincide with it. Hence, there will always be small differences and it cannot be excluded that these could be detectable. Although not much progress has been made in this connection, it is worth mentioning the curious fact that the differential equation, $df/dx = ax(1 - x)$, produces a very neat continuous solution, whereas the analogue difference equation, $\Delta f/\Delta x = ax(1 - x)$, depending on the value of the parameter a, produces chaotic effects. See Van Bendegem [2000] and Welti [1987], pp. 516-518.

In the second case there is a strong tendency to focus on the problem whether elements from the mathematical model can be either directly or indirectly linked to the physical constants. All things considered it seems not very interesting to look for direct connections. Suppose that one would be tempted to identify the hodon with the Planck length, $l_p = 10^{-35}\ m$ and the chronon—the smallest time unit—with Planck time, $t_p = 10^{-43}\ s$, then, if it is accepted that an object can only move through neighbouring hodons, then there is a upper limit to velocities, namely $c = 3.10^8 m/s$. But if an object is not moving at the top speed of one hodon per chronon, then the next lower value must be one hodon per two chronons, but that means a velocity of $c/2$. We seem to have missed out the whole range between $c/2$ and c. There is a way out, but it supposes that ‘jerky’ motion is considered possible, an aesthetically quite ugly idea. An object moves two hodons in two chronons and then waits for one chronon and then repeats the same motion. The average velocity is then $2c/3$.

Nevertheless some philosophers and physicists seem especially interested in this kind of approach, see, e.g., Hahn [1934], Biser [1941], Coish [1959], Finkelstein & Rodriguez [1986], Meessen [1989], Buot [1989], to name but a very few. For the period 1925-1936, Kragh and Carazza [1994] is an excellent overview showing that many physicists were playing around with finitist ideas. Two types of arguments and considerations are often expressed:

The quantum mechanical connection. A strict finitist geometry makes sense because it is clear in quantum mechanics that discreteness is an essential feature of the world and hence should be reflected in our descriptions of that world. Although at first sight the argument seems plausible, it seriously underestimates the difficulty of the task. It is therefore not very surprising that in nearly all cases only

rough suggestions are made and it is rather unclear what mathematical formalism could replace the existing mathematics used in quantum mechanics involving lots of infinities (such as infinite dimensional Hilbert spaces).

The numbers game. In this approach the focus is on the physical constants themselves including such constants as the velocity of light *c*, the Planck constant *h*, the mass of the electron m_e, and so on. As these values are necessarily finite, it seems worthwhile to investigate whether a finitist approach can explain why these constants have the values they happen to have. A very fine example of such an approach is the so-called *Combinatorial Physics Program*. Starting from a very simple model, combinatorial considerations on the size of certain mathematical objects lead to an estimation of some physical constants. The success of this program is rather modest as these models do not connect easily to existing physical theories. A self-contained presentation of this program is to be found in Bastin & Kilmister [1995]. There is a very strong similarity with the work of A. S. Eddington. Not very surprisingly, a presentation of the work of Eddington on his fundamental theory has been written by Kilmister [1994].

All things considered, both on the mathematical as on the physical level an enormous amount of work remains to be done. Probably the best way to characterize the present-day situation is that some 'famous' objections to a finitist approach in geometry have been (partially) answered so that it is legitimate to continue this research program.

Supplement to Finitism in Geometry

Finite Fields as Models for Euclidean Plane Geometry

Finite Fields

A field is a set F equipped with two operations +, · such that

a. the pair <F,+> is a group, i.e.,

+ is closed:	$\forall x,y \exists z(x + y = z)$
+ is associative:	$\forall x,y,z(x + (y + z) = (x + y) + z)$
there is a neutral element:	$\forall x(x + 0 = x)$
every element has an inverse:	$\forall x \exists y(x + y = y + x = 0)$

b. likewise <F,·> is a group, the neutral element being 1
c. the following distributivity laws hold:

$\forall x,y,z(x \cdot (y + z) = (x \cdot y) + (y \cdot z))$
$\forall x,y,z((x + y) \cdot z) = (x \cdot z) + (y \cdot z))$

It is straightforward to see that the real numbers $\mathbb{R}$ with the usual addition and multiplication is a field. In this case the set F is infinite, but F can be finite as well. Then we have a finite field or a Galois field. There is however one very important distinction between a field such as $\mathbb{R}$ and a Galois field. In the latter, given the multiplicative neutral element 1, there is a prime number p such that $p \cdot 1 = 0$. p is called the characteristic of the field. It can be shown that if p is the characteristic of a field, then it must have p^n elements, for some natural number n. In addition Galois fields are the only finite fields.

> *Example*: the Galois field with characteristic 3 and number of elements 3, *GF*(3) for short.

The tables for addition and multiplication tell the whole story:

+	0	1	2

0	0	1	2
1	1	2	0
2	2	0	1

·	**0**	**1**	**2**
0	0	0	0
1	0	1	2
2	0	2	1

In the first case, 1 + 1 + 1 = 0.

It is easy to see that the above tables correspond to addition and multiplication modulo p. In other words, in the field $a = b$ if and only if $a \equiv b$ (mod p).

Euclidean Axioms in a Finite Field

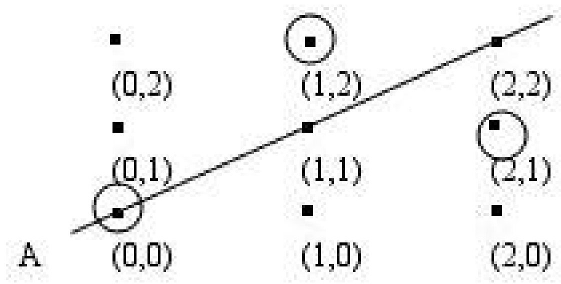
To see how a finite field can be a model, I will take the incidence relation. The axioms for the incidence relation are:

a. Through two points exactly one straight line can be drawn.
b. There are at least two points on every straight line.
c. There are at least three points that are not on the same straight line.

In case we take $GF(3)$ as a possible model, then to a point p corresponds to a couple (x,y), such that $0 \leq x,y \leq 2$. A line corresponds to a triple (a,b,c), such that $0 \leq a,b,c \leq 2$ and at most one of $a = 0$ or $b = 0$, or, equivalently, at most one of $a \equiv 0$ or $b \equiv 0$ (mod 3). The incidence relation is translated as follows: a point p lies on a line A iff if (x,y) corresponds to p and (a,b,c) corresponds to A, then the equation $ax+by+c = 0$ is satisfied, or, equivalently, $ax+by+c \equiv 0$ (mod 3) is satisfied. Some facts are now straightforward to check:

i. There are exactly p^2 points.
ii. There are exactly $p(p+1)$ straight lines.
iii. On every straight line there are exactly p points.
iv. Through every point pass exactly $p+1$ straight lines.
v. The axioms (a), (b) and (c) are true in this model.

A graphical representation could look like this:



The line indicated by *A* corresponds to $x = y$. This seems to correspond nicely to the classical Euclidean case. However something strange happens with the linear equation $x + y = 0$. In the drawing the 3 points that are on this line have been circled. As must be clear these lines are ÒbadÓ and should be "ignored" in the model.

In order to satisfy the remaining axioms further restrictions are required on the size of the domain. These will just be mentioned without details:

a. p must have the specific form $4n+3$ (and not $4n+1$).
b. p must in addition have the specific form $8mq_1q_2...q_k - 1$, where q_i is the i-th odd prime (so $q_1 = 3$) and m a positive integer.

The second condition that is needed to guarantee the existence of the Euclidean "kernel" is a non-trivial statement. It actually requires some essential parts of number theory to prove that there are prime numbers of that form. There are, classically speaking, an infinite number of them. By choosing p large enough, one can make the ‘kernel’ as large as one desires to have the Euclidean approximation as close as one wants.

Note: As Ernst Welti points out, it would be a rather annoying situation for a finitist if the proof that shows that there are an infinite number of primes of the right form were not finitistically acceptable. Although the original proof of Dirichlet was in fact unacceptable, fortunately there does now exist a finitistically acceptable proof of the theorem.

Impartiality

Impartiality is sometimes treated by philosophers as if it were equivalent to *moral* impartiality. Or, at the very least, the former word is often used, without the qualifying adjective 'moral', even when it is the particularly moral concept that is intended. This is misleading, since impartiality in its broadest sense is best understood as a formal notion, while moral impartiality in particular is a substantive concept -- and one concerning which there is considerable dispute. This entry will be predominantly concerned with moral impartiality -- the sort of impartiality, that is, that properly features in normative moral and political theories. We begin, however, by addressing the broader, formal concept.

1. The concept of impartiality

The most common mistake made by philosophers in their use of the words ‘impartial’ and ‘impartiality’ is that of assuming that such words denote a positive, unitary concept -- presumably a concept closely linked with, if not identical to, morality. This, however, is simply not the case. Rather, there are various sorts of behavior that may be described as ‘impartial,’ and some of these obviously have little or nothing to do with morality. A person who chooses an accountant on the basis of her friends’ recommendations may be entirely impartial between the various candidates (members of the pool of local accountants) with respect to their gender, their age, or where they went to school. Yet if her choice is motivated solely by rational self-interested considerations then it is clear that the impartiality she manifests is in no way a form of *moral* impartiality. To take a more extreme case, consider an insane serial killer who chooses his victims on the basis of their resemblance to that some celebrity. The killer may be impartial with respect to his victims’ occupations, religious beliefs, and so forth, but it would be absurd to regard this as a form of *moral* impartiality (despite the fact that, in certain contexts, morality does require impartiality with respect to such considerations.)

It is also worth noting that some types of impartiality may in themselves be immoral or morally questionable. Suppose that I decide to pass along a treasured family heirloom to one of my two sons, Bill and Phil. Flipping a coin would constitute one type of impartial procedure for choosing between the two. But suppose that I have already promised the heirloom to Phil, on several occasions. In this case it would be quite wrong to allow a coin toss to determine whether he gets it. Deciding by means of a coin toss would be an impartial procedure, but it would be the wrong sort of impartiality here, for it would ignore the moral obligation created by my previous promises.

It is important, then, to recognize that *moral* impartiality is a particular species of impartiality, and that the latter, unqualified, denotes a much broader concept. In this broad sense, impartiality is probably best characterized in a negative rather than positive manner: an impartial choice is simply one in which a certain sort of consideration (i.e. some property of the individuals being chosen between) has no influence. An analysis along these lines has been proposed by Bernard Gert. Gert’s analysis holds that "A is impartial in respect R with regard to group G if and only if A’s actions in respect R are not influenced at all by which member(s) of G benefit or are harmed by these actions" (Gert 1995, p.104). Thus, for Gert, impartiality is a property of a set of decisions made by a particular agent, directed toward a particular group.

Gert’s analysis captures the important fact that one cannot simply ask of a given agent whether or not she is impartial. Rather, we must also specify with regard to whom she is impartial, and in what respect. Gert’s analysis, then, permits and indeed requires that we make fairly fine-grained distinctions between various sorts of impartiality. This is necessary, since one and the same agent might manifest various sorts of partiality and impartiality towards various groups of persons. Consider, for instance, a university professor who is also a mother of five children, and who is currently acting as a member of a hiring committee. Such an agent might be impartial between her children with respect to the care they receive (while preferring her own children over others in this respect), and also impartial between the various job candidates; but it is clear that these two uses of the word ‘impartial’ denote very different practices. In particular, the idea of merit applies in one case but not the other: to be impartial between job candidates is presumably to select between them on the basis of merit, whereas to be impartial between one’s children

is *not* to think of merit at all, but rather to provide equal protection and care to all.

Many attempts to characterize impartiality fail to respect the distinction between the broadest, most formalistic sense of the notion, and a more specifically *moral* impartiality. To say, for instance, that an impartial choice is one that is free of bias or prejudice is to presuppose that we are dealing with a certain sort of impartiality, that which is required or recommended by morality, or at least worthy of moral approbation. ‘Bias’ and ‘prejudice’ are loaded terms, suggesting not only that some consideration is being excluded, but also that the exclusion is appropriate and warranted. Similarly, the idea that impartiality requires that we give equal and/or adequate consideration to the interests of all concerned parties goes well beyond the requirements of the merely formal notion. (In the coin toss case, it is quite clear that Phil’s claims to the heirloom are *not* being given equal or adequate consideration.) As a characterization of *moral* impartiality, however, this suggestion is considerably more promising.

2. Morality and impartiality

2.1 The impartial point of view

It is generally agreed that some sort of close connection obtains between morality and impartiality. Indeed, the phrases ‘moral point of view’ and ‘impartial (or ‘impersonal’) point of view’ are sometimes used interchangeably to refer to the imagined impersonal perspective from which, it is supposed, moral judgments are to be made (Baier 1958, chapter 8; Harsanyi 1982; Scheffler 1982, 1985; Smith 1976 [1759]; Wolf 1992; see also Blum 1980, Chapter 3). As noted above, however, the word ‘impartial’ is a general term with many particular species; it follows from this that the phrase ‘impartial point of view’ is itself ambiguous. At most, it might be that the moral point of view constitutes *one sort of* impartial point of view.

Even this claim, however, faces difficulties. While impartiality may play a significant role in moral behavior, it is not clear that it is sufficient to exhaust the demands of morality. Treating a person appropriately and respectfully may well require certain sorts of emotional and/or cognitive responses: sensitivity to her needs and values, empathy for her suffering, and the like. But if these responses are pictured as the results of *positive* traits or attributes (and not simply as, say, the result of a lack of bias or prejudice), then it is not clear that merely being impartial between persons is sufficient to guarantee that one will possess and display the necessary sensitivities. Indeed, characterizations of impartial agents which proceed in negative terms (that is, by defining various preferences, emotions or bits of information that she does not possess or that do not move her) often risk picturing the impartial agent as impersonal and even indifferent (Henberg 1978; Brandt 1954).

A second problem for the claim that the moral point of view is identical with (some version of) the impartial point of view -- or indeed, for any view which identifies morality and impartiality -- is that it seems plausible to regard some forms of moral partiality as morally admirable, and perhaps even morally required (Blum 1980; Cottingham 1983, 1986, 1996; Jeske & Fumerton 1997; Jollimore 2001; Kapur 1991; Kekes 1981; MacIntyre 1984; Oldenquist 1982). Loyalty to one’s family, community or country,

for instance, is commonly regarded as a virtue. Yet such an attitude is a clear and indeed paradigmatic example of partiality, requiring that an agent feel and act differently toward one set of persons than she does toward humanity in general. Similarly, certain specific moral duties arising from certain particular relationships seem to involve partiality in an irreducible manner. Parents, for example, are thought to be morally obliged to take special care of their own children; to regard one's child as merely one among millions would be regarded as highly eccentric if not monstrous. Of course, some moral duties do require that an agent be impartial in performing them. But on common sense moral views at least, impartiality seems mostly to be required in the context of specific roles -- such as when a person is acting as a judge, an umpire, or a representative of some public institution (Baron 1991; Blum 1980; Cottingham 1983). The idea that impartiality is a pervasive and universal moral requirement seems to contradict our ordinary moral intuitions.

Whether there exists such a thing as morally admirable partiality is the main issue that separates the so-called *partialists* from the *impartialists*. Partialists, in general, tend to claim that morally admirable partiality does exist, that it cannot be reduced to any form of impartiality at a more fundamental level, and that these facts pose a serious problem for those who claim that morality and (some form of) impartiality are identical, or even closely related. Impartialists, by contrast, either deny the existence of morally admirable partiality altogether, or hold that any apparent cases are in fact ultimately reducible to impartial standards (see section 6). Thus impartialists hold that -- contrary, perhaps, to appearances -- impartiality is, indeed, a pervasive and universal requirement of morality.

2.2 The ideal observer theory

Rather than being put in terms of an impartial *point of view*, the relation between morality and impartiality is sometimes made out in terms of an impartial *agent* or *observer* -- a person who makes moral judgments without being influenced by the sort of contaminating biases or prejudices that tend to arise from the occupation of some particular point of view. (Smith 1976 [1759]; Hume 1978 [1740]; Firth 1952; Brandt 1954; Hare 1989.) (We should note that this idea is not always clearly distinguished from the conception based on the impartial point of view; Smith 1976 [1759], for instance, seems to advance them both at once, in claiming that the ideal observer simply is the observer who occupies the ideal point of view.)

The observer may also be defined as 'ideal' in various other ways. It is generally stipulated that she is in possession of all the nonmoral facts that are relevant to the judgments she has to make (Firth 1952). It is also fairly common to assume that she is an ideal reasoner, and thus be immune to logical fallacy or mistaken inference, etc. (Indeed, Hare goes so far as to state that his "archangel" possesses "superhuman powers of thought, superhuman knowledge and no human weaknesses" (Hare 1989, p. 44).) The 'ideal observer theory' of morality, in its most straightforward form, states that moral judgments simply are the judgments an ideal observer of this sort will make.

What must be pointed out about such a conception of morality, for our purposes, is that any advantage it has over the conception of morality as an impartial point of view presumably arises from the fact that the ideal observer is not completely defined in terms of impartiality. (If she were, the two conceptions would

simply coincide.) Yet many ideal observer theorists seem to accept a characterization of the ideal observer which concentrates on her impartiality and impersonality. Firth, for example, suggests that the ideal observer is both "distinterested," in the strong sense of being "entirely lacking in particular interests," and "dispassionate," in that she is "incapable of experiencing any emotions at all." (Firth, 1952) Defined in this way, however, the ideal observer sounds not only impersonal but deeply indifferent; and the idea that the moral judgments of a person who had neither emotional responses nor particular interests could be trusted, let alone that they might be considered definitive of morality, strikes some critics as highly implausible (Brandt 1979).

Suppose, then, that the ideal observer theorist decides that the definition of the ideal observer *must* include more than the bare idea of impartiality -- that in addition the observer must be, say, compassionate (and thus not indifferent); and that she must possess a considerable facility for proper moral judgments -- practical wisdom, in the Aristotelian sense. Such a theorist will now face a different problem: the more we build into the definition of our ideal observer, the less useful it becomes as a heuristic device. Stipulating that ideal observer is very wise, for example, is not very helpful if we ourselves are not wise, and so have no idea what an ideally wise observer would choose. Indeed, ideal observer analyses that go too far in this direction seem to become circular -- the ‘ideal’ observer is ideal because she always makes proper judgments, those being defined as just those judgments the ideal observer would make (Broad 1959, p. 263). John Stuart Mill seems to commit an error of this sort when he writes:

> Impartiality, in short, as an obligation of justice, may be said to mean, being exclusively influenced by the considerations which it is supposed ought to influence the particular case in hand; and resisting the solicitation of any motives which prompt to conduct different from what those considerations would dictate. (Mill 1861/1992, p. 154; see also Firth 1952, p. 336)

The ideal observer, then, to be useful, must be given some independent definition, and not simply defined as ‘an agent who always gets it right.’ The challenge, of course, is to find such a definition. Here, as with the conception of morality as defined by an impartial point of view, the phenomenon of morally admirable partiality proves a particularly difficult issue. Should we define the ideal observer as being loyal to her country, or as being above loyalty? If the former, can she serve as an adequate moral example to people who do not share her allegiances? If the latter, how can she serve as an adequate example to *anyone?* The persistent problem that faces the ideal observer approach to moral impartiality seems to be that any process of idealization of the sort required to make such a conception work seems likely to result in an individual so removed from the concrete lives and concerns of actual human moral agents, that her moral judgments will turn out to be in large part irrelevant to the question of how such agents ought to live (see Walker 1991).

2.3 Moral impartiality and equality

The moral importance of the impartial point of view is that from it, every moral agent counts equally: no one, including the person occupying that point of view, is considered to be intrinsically more significant

than anyone else, or to have more powerful claims to attention simply by virtue of who they are. Similarly, one of the primary virtues of the ideal observer seems to be that she also regards persons in this way. Whatever these conceptions may get wrong, then, one thing they seem to get right is the idea that there is a close and important connection between moral impartiality and equality (see especially Nagel 1991, Chapter 7).

Some clarification, however, is required. To say that from the impartial point of view, no one is seen as *intrinsically* more significant than anyone else, is not to say that there is no reason *whatsoever* for which a person might count as more significant than others, or for which a person might legitimately demand disproportionate moral attention in some circumstances. Many moral theorists, after all, will suppose that from the impartial point of view, properly conceived, some individuals *will* count as more significant, at least in certain ways. William Godwin (Godwin 1793) provides an influential, and rather infamous, example. Fenelon, the archbishop of Cambrai, Godwin writes, may be supposed to be more significant than a mere chambermaid, and it follows -- at least according to Godwin -- that in the case of a fire, the archbishop ought to be rescued first. The reason, however, is not simply that the archbishop happens to be *himself* -- that is, his greater significance is not supposed to be intrinsic; rather, the claim is grounded on the fact that the archbishop makes greater contributions to society:

> We are not connected with one or two percipient beings, but with a society, a nation, and in some sense with the whole family of mankind. Of consequence that life ought to be preferred which will be most conducive to the general good. In saving the life of Fenelon, suppose at the moment when he was conceiving the project of his immortal *Telemachus*, I should be promoting the benefit of thousands who have been cured by the perusal of it of some error, vice and consequent unhappiness. Nay, my benefit would extend further than this, for every individual thus cured has become a better member of society and has contributed in his turn to the happiness, the information and improvement of mankind. (Godwin 1793, 41-42)

The claim that the archbishop is more significant, then, is grounded on what are essentially universal properties: if the chambermaid also had it in her to write *Telemachus*, her claim to be rescued would be just as great. Fenelon's claim to priority is not based on his *intrinsic* significance. In Godwin's mind, the fact that one individual has a greater claim to rescue than the other is not only not in conflict with impartiality, but indeed is implied by impartiality, for it is based on the (alleged) fact that an impartial judgment of their worth attributes more to one than to the other.

Thus, viewing persons from an impartial point of view need not imply that we view them equally, in every sense of the word; and it certainly does not imply that everyone must receive *equal treatment.* (In Godwin's Archbishop Fenelon, if we assume that only one person can be saved, the only way to give the archbishop and the chambermaid equal treatment would be to let them both perish in the flames.) What impartiality seems to require is not that everyone receive equal treatment, but rather that everyone be *treated as an equal* (Dworkin 1977, p. 227). While the distinction between equal treatment and treatment as equals is difficult to make out with precision, the main idea is fairly clear: treatment as equals requires that persons are *not* treated equally, but rather treated in accordance with what rights they possess, what

legitimate claims they put forward, and, in general, with what they deserve. Thus, to inflict a one year jail sentence on all accused persons, regardless of whether they are guilty or innocent, is to provide equal treatment to members of that group; but it is not to treat them as equals.

Whether or not moral impartiality obliges us to see the archbishop as having a greater claim to be rescued is, of course, controversial. Moreover, Godwin asserts two even more controversial claims in connection with the Archbishop Fenelon example. The first is that the chambermaid *herself* ought to have perceived the greater significance of the archbishop, and so should have sacrificed her own life for his, were that necessary. The second is that any other person -- even the child or husband of the chambermaid -- ought to have been willing to make the same sacrifice:

> Supposing the chambermaid had been my wife, my mother or my benefactor. That would not alter the truth of the proposition. The life of Fenelon would still be more valuable than that of the chambermaid; and justice -- pure, unadulterated justice -- would still have preferred that which was most valuable. Justice would have taught me to save the life of Fenelon at the expense of the other. What magic is there, in the pronoun "my" to overturn the decisions of everlasting truth? My wife or my mother may be a fool or a prostitute, malicious, lying or dishonest. If they be, what consequence is it that they are mine? (Godwin 1793, pp. 41-42)

Whether this extreme position really is required, either by moral impartiality or by the demand that we treat people as equals, is a matter of great dispute, not only between partialists and impartialists but within the impartialist camp itself. If nothing else, Godwin's position is quite clearly incompatible with the apparent existence of morally admirable partiality. (Williams (1981) holds that even to consider sacrificing one's wife for the sake of impersonal justice constitutes a kind of moral error in its own right.) Moreover, despite the fact that the ultimate evaluation is made on the grounds of perfectly general properties, it is not entirely clear that the objects of the evaluation really are being treated as equals, in the relevant sense -- the fact that the chambermaid's life is to be sacrificed for the greater good at least suggests that her standing as a moral being is not really being taken into account, and that the suggested understanding of moral impartiality is therefore deficient. These issues, which we will return to in section 3.2 and in section 6, are at the heart of the contemporary debate about moral impartiality.

3. Moral impartiality (1): Consequentialist moral theories

3.1 The nature of consequentialist impartiality

Consequentialist moral theories hold that moral evaluations and justifications must ultimately be grounded in the value of the consequences of the actions, rules, policies, strategies, character traits, etc. that are being evaluated (Hooker 1994). That is, the ultimate question to be asked of any action, rule, or character trait under evaluation is, "Does it [the action, rule, or trait in question] promote the good?" For

the purposes of this entry, three important assumptions will be made regarding consequentialist theories. First, consequentialist theories will be assumed to hold that the overall values of sets of consequences can be determined, and thus ranked, independently of the identity of any particular agent (thus, we can speak of the "best" consequences without having to ask, "best for whom?") Second, such theories will be assumed to hold that the impersonal good (i.e. the overall value of some particular state of affairs) is largely if not entirely composed of the interests of individual persons, and that the interests of each person count for just as much as those of every other person. Finally, it will be assumed that we are dealing with *act* consequentialist theories -- theories, that is, which hold that the consequentialist standard is to be applied directly to the actions of agents, and that what is required is that every action (or overall pattern of action) *maximize* the impersonal good. Such a theory, then, requires that every agent always choose an action that will bring about consequences at least as good as those that would be brought about by any other available action. (It should be noted that rule consequentialism, which holds that the consequentialist standard is to be applied to rules of action rather than directly to actions themselves, is excluded by this set of assumptions. Rule consequentialism does incorporate a significant form of moral impartiality, but it is not the sort that is incorporated by more traditional act consequentialist theories (Howard-Snyder 1993).)

Together, these three assumptions regarding the nature of consequentialism result in a theory which, on the surface at least, seems to place each agent under a pervasive obligation to be strictly impartial between all persons, by requiring her always to exclude from her practical deliberations (almost) all considerations that do not bear directly on the ways in which people's interests might be advanced or injured by her actions.

The consequentialist standard, then, is strictly impartial in a very rigorous sense. A consequentialist agent is not permitted to prefer herself, nor any of her loved ones, in choosing a distribution of benefits and burdens. She may not accept a pleasure for herself if doing so involves passing up the opportunity to bring about a slightly larger pleasure for a stranger. Nor is she permitted to feed her own children if she could do more good by feeding hungrier strangers instead. She must sacrifice the life of a spouse, parent or child if, by doing so, she would save more lives, or even save the life of one other person whose contribution to the overall good would be greater than that of the person sacrificed. (Recall Godwin's Archbishop Fenelon case, discussed in section 2.3.) It is for reasons such as this that consequentialist impartiality is accused of being too demanding. By refusing to allow the agent's personal concerns to play a special role in her practical deliberations, it is claimed, consequentialism threatens her integrity and alienates her from herself and others (Kapur 1991, Scheffler 1982, Stocker 1976, Williams 1973, 1981). As Brian Barry has written, the effect of consequentialist impartiality "is, in effect, to extend to the whole of conduct the requirements of impartiality that on the common-sense view are restricted to judges and bureaucrats acting in their official capacities." (Barry 1995, p. 23) The kind of impartiality that features in consequentialist theories, then, seems to be much more pervasive, and much more severe, than that recommended by common sense morality.

3.2 Is consequentialist impartiality too demanding?

The fact that consequentialist impartiality turns out to have such strict and demanding implications is, for

the consequentialist, a double-edged sword. On the one hand, there is no doubt that consequentialism is a deeply impartial moral theory; on the plausible and popular assumption that a moral theory *must* be deeply impartial, consequentialism meets this criterion with flying colors. And consequentialists have typically been adept at exploiting this fact with powerful rhetoric (Godwin's famous query, 'what magic is there in the pronoun 'my'?' being a noteworthy example.) On the other hand, the impartial demands of consequentialism are so strict and so extreme that some critics have found them unacceptable: consequentialism, they claim, simply demands too much and must therefore be rejected (Scheffler 1982, Slote 1985, Williams 1981).

Essentially, this worry is a version of what we referred to above as the puzzle of morally admirable partiality. The common-sense view is that it is permissible for an agent to be partial toward herself; that is, to treat her own projects and concerns as if they had special significance (Scheffler 1982). (From her point of view of course, they *do* have special significance.) This sort of self-concern, then, constitutes a form of partiality which seems, from the vantage point of common sense, to be morally endorsed. Similarly, certain sorts of partiality directed toward *other* people -- friends, family members, and the like -- are also forbidden by consequentialist impartiality, but regarded as justifiable, and in many cases admirable, from the standpoint of common sense (Blum 1980, Cottingham 1983, Kekes 1981, Slote 1985).

Defenders of consequentialism generally respond in one of three ways. First, a consequentialist might argue that *any* genuinely impartial moral theory will make extreme demands of agents. Second, they might argue that even though it is not necessary for a genuinely impartial theory to make extreme demands, the fact that it does is no grounds for an objection against it. Third, they might argue that in fact, the demands of consequentialism are not as extreme as have been supposed.

The first strategy faces a severe difficulty: namely, it at least seems to be the case that certain non-consequentialist moral theories -- in particular, deontological theories -- also incorporate impartial elements in a fundamental manner, and yet make demands on the moral agent which are considerably less extreme than those of consequentialism. Thus, while some consequentialists (e.g. Brink 1989) have argued that the truth of consequentialism can be logically derived more or less directly from the requirement that morality be impartial, this seems to be a mistake (Scheffler 1992, pp. 105-109). Of course, it is open to the consequentialist either to deny that deontological moral theories are *genuinely* impartial (Kagan 1989; Scheffler 1982, 1985), or to argue that, properly understood, any plausible ethical theory will be seen to make demands comparable to those made by consequentialism (Brink 1989, Ashford 2000). Both of these strategies, however, face difficulties; as we will see in section 4, there is in fact a very strong case in favor of viewing at least some deontological theories as genuinely and fundamentally impartial -- a case which nevertheless does not prohibit us from viewing such theories as less demanding than their consequentialist rivals.

The second strategy is to argue that those who object to consequentialism on the grounds that it is too demanding are placing too much importance on the role of morality in practical reasoning (Brink 1989; Wolf 1982, 1992). If moral considerations dominated practical reasoning -- if, that is, they were the only or at any rate by far the most significant considerations in determining our actions -- then

consequentialism would be untenable, on account of its demanding too much. A proper perspective on practical reasoning, however, reveals that moral demands constitute only one set of demands among many. When put in their proper place then in the larger scheme of practical reasons and requirements, the extreme demands of consequentialist morality will no longer seem threatening. To borrow a pair of phrases from David Brink, what appear to be "moral worries" about the tendency of consequentialism to make excessive moral demands, might really be "worries about morality" -- worries, that is, about whether or not we have reason to act as morality requires. Whether the view of morality presupposed by this strategy is true, however, is questionable; at the very least, it does not seem to be the case that the majority of those who have defended consequentialism as a normative theory of ethics have intended it to be viewed as a theory that could be frequently or easily overridden (Jollimore 2001, Chapter 3; Peter Railton (1984) and Richard Miller (1992, Chapter 10) also express doubts about this approach).

The third strategy is perhaps the best known and most frequently employed. It is argued that, given a reasonable and accurate view of human nature and the abilities of agents, it will be seen that what consequentialism requires is *not* a radically different sort of life from the one most of us currently live; rather, consequentialism will require (in most cases, at least) only reasonable, and relatively minor, adjustments in our current lifestyles. In particular, it is argued that consequentialism permits the agent both to give preference to her own projects and concerns, and to favor particular other individuals (friends, family members, etc.), and that all this is consistent with the agent's having as her overriding project the maximizing of the good. The *locus classicus* of this argument is found in Mill's *Utilitarianism:*

> The objectors to utilitarianism cannot always be charged with representing it in a discreditable light. On the contrary, those among them who entertain anything like a just idea of its disinterested character, sometimes find fault with its standard as being too high for humanity. They say it is exacting too much to require that people shall always act from the inducement of promoting the general interests of society. But this is to mistake the very meaning of a standard of morals, and to confound the rule of action with the motive of it […] The great majority of good actions are intended, not for the benefit of the world, but for that of individuals, of which the good of the world is made up; and the thoughts of the most virtuous man need not on these occasions travel beyond the particular persons concerned, except so far as is necessary to assure himself that in benefiting them he is not violating the rights -- that is, the legitimate and authorized expectations -- of any one else. The multiplication of happiness is, according to the utilitarian ethics, the object of virtue: the occasions on which any person (except one in a thousand) has it in his power to do this on an extended scale, in other words, to be a public benefactor, are but exceptional; and on these occasions alone is he called on to consider public utility; in every other case, private utility, the interest or happiness of some few persons, is all he has to attend to. (Mill 1992 [1861], pp. 64-66.)

Similarly, Godwin (1968 [1801]) argues that

> True wisdom will recommend to us individual attachments […] since it is the object of

> virtue to produce happiness; and since the man who lives in the midst of domestic relations will have many opportunities of conferring pleasure, minute in the detail, yet not trivial in the amount. (Quoted in Cannold, *et al*., 1995)

(This position, of course, appears to be in some amount of tension with the more extreme consequentialist position attributed to Godwin in section 2.3).

More recent versions of this argument follow Mill's basic strategy. Peter Railton (1984) argues that a "sophisticated" consequentialist will develop patterns of decision-making that do not, except on rare occasions, refer explicitly to consequentialist aims and goals, and that both the psychology and the outward behavior of such an individual will be similar to that of the typical non-consequentialist. Similarly, Frank Jackson (1991) argues that the most efficient strategy for a dedicated consequentialist is to concentrate on small groups of particular persons, rather than trying to promote the well being of humanity at large, and that this will involve the formation of close personal relationships with other individuals. Others who have deployed versions of this argument include Bales (1971), Brink (1989), and Pettit & Brennan (1986).

The evaluation of this consequentialist strategy is a difficult issue. Consequentialists are surely correct to point out that obsessive consequentialist strategizing is likely, at a certain point, to turn counter-productive, and that a consequentialist agent is therefore well-advised to develop more moderate approaches. On the other hand, Mill and many other consequentialists seem to underestimate the amount of good that a dedicated consequentialist agent might be able to contribute, and thus, to underestimate the amount of good that she will be *required* to contribute. Moreover, our powers to influence the lives of strangers have increased considerably since Mill's day. As Susan Wolf writes, "[T]his argument is simply unconvincing in light of the empirical circumstances of our world. The gain in happiness that would accrue to oneself and one's neighbors by a more well-rounded, richer life than that of the moral saint would be pathetically small in comparison to the amount by which one could increase the general happiness if one devoted oneself explicitly to the care of the sick, the downtrodden, the starving, and the homeless" (Wolf 1982, p. 428; see also Singer 1972). It is not clear, then, that an appeal to the limits of human powers can succeed in converting what is, after all, a fundamentally radical moral theory, into a comfortably conservative one.

3.3 Consequentialist impartiality and justice

In addition to claiming that consequentialist impartiality is too demanding, many critics have also argued that it is too permissive. Since consequentialism makes the permissibility of an action entirely dependent on the value of that action's consequences, it follows that there is no *type* of action that can be prohibited on consequentialist grounds (except, of course, for that "type" which is defined explicitly in terms of sub-optimal consequences.) Thus instances of torture, premeditated murder, rape, and other violations of fundamental human rights are at least potentially justifiable on a consequentialist basis; no such action can be ruled out, morally speaking, until the comparative value of the state of affairs it will bring about has been determined.

The effect of this complaint, like the previous one, is not to deny the claim that consequentialism is a deeply impartial moral theory, but rather to suggest that it incorporates the wrong sort of impartiality. Suppose, to take an example common in the literature, that consequentialism recommends that an man be convicted of, and punished for, a crime he did not commit, in order to prevent the public from rioting (McCloskey 1963). Such an action would, according to common intuitions, constitute a gross violation of justice; and it seems a weak reply to point out that the recommendation was arrived at through an impartial calculation -- a calculation that took the interests of every individual (including the framed man) into equal account. For while the claim is, strictly speaking, true, there is nevertheless a clear and compelling case in favor of concluding that the framed man was *not* treated impartially, in the sense that ought to matter here. We expect a judicial system to allocate punishments in accordance with degree of guilt, not in accordance with the expected value to society of the consequences in each case; and the fact that both methods constitute forms of impartial decision-making does not imply that they are equally morally acceptable.

Again, the classic response to this objection dates back to Mill's *Utilitarianism* (1992 [1861]). If institutions of justice are to be given a general justification, Mill argues, this justification must find its ultimate grounding in utility to society; for what else could explain why justice is valued at all, other than the fact that it serves and protects our interests? But since a justice system will only succeed in this role if it is governed by common principles of justice -- principles including, for instance, that only the guilty should be punished, and that the punishment ought to be proportional to the crime -- it follows that such principles are not opposed to consequentialism at all. Rather, at the deepest justificatory level, consequentialism and the demands of justice coincide.

The claim that such a coincidence generally obtains is probably easy to establish. The challenge for Mill, and for other consequentialists, arises in those particular cases in which the coincidence fails. Assuming that the possibility of such cases does not move one to simply abandon consequentialism in favor of some more justice-friendly conception (such as the rule consequentialism Mill himself sometimes seems to find attractive), there are two general defense strategies for consequentialists to employ. The first strategy argues that there are good consequentialist reasons for being the sort of agent who respects the dictates of justice even in cases in which the coincidence between the demands of justice and those of consequentialism fails (Pettit 1997; cf. Railton 1986). The second strategy admits that there are cases in which unjust actions can be given a consequentialist justification, but holds that when so much as it stake, justice must give way to consequentialism's demands (Smart 1973; Kagan 1989; Pettit 1997). Whether either approach is sufficient, given the apparent depth and force of our common intuitions about the requirements of justice, is a matter of ongoing debate.

4. Moral impartiality (2): Deontological moral theories

4.1 Deontological impartiality and the personal point of view

In section 3.2 we noted that while consequentialist impartiality is one possible interpretation of the demand that morality be impartial, it is not by any means the only available interpretation; nor is it clearly the most plausible. The considerations related to justice discussed in section 3.3 may help us to appreciate this. For consider once more the position of the framed innocent, whose fundamental interests have been sacrificed for the sake of the greater good. Such a person may well complain that he has *not* been treated impartially, in the appropriate sense; for, while it is true that his interests were counted in determining the nature of the overall good, it is nevertheless also true that ultimately, he became the victim of a form of abuse that was both harsh and undeserved. The framed innocent might also back up his complaint by making the plausible claim that, had he been in a position to choose, he would never have consented to a moral system that allowed *anyone* to be accorded such treatment. Thus, while there is a sense in which his interests were counted equally, there is another and very important sense in which his interests -- and perhaps more importantly, his claims and rights -- do not seem to have received full or adequate consideration at all.

Deontologists insist that consequentialism errs by failing to accord proper significance to the moral agent as an individual; in John Rawls' words, consequentialism "does not take seriously the distinction between persons" (Rawls 1971, section 5). (Rawls has utilitarianism in particular as his target, but the point applies more widely.) The fact that consequentialist impartiality makes extraordinary and, to many, unreasonable demands on the individual (section 3.2) indicates that consequentialism fails to take individuals seriously as *agents*. And the fact that consequentialist impartiality permits the individual to be used as a mere means when doing so promotes the greater good (section 3.3) indicates that consequentialism fails to take individuals seriously as *patients*. The conception of impartiality that tends to be favored by deontologists avoids such implications by refusing to view impartial action simply as a matter of maximizing interests (or some other version of the impersonally determined good.) Indeed, deontologists take *the right* rather than *the good* to be fundamental to ethics, and tend to see moral action in terms of acting in accordance with principles that are rationally acceptable to all.

Exactly what these principles are, and exactly what method should be used to determine them, are matters of some disagreement among deontological theorists. But there does seem to be a general consensus among deontologists that moral impartiality does *not* require that an agent be strictly neutral between her own good and the good of other people in ordinary decision-making contexts. Rather, an agent is permitted on deontological views to give special attention to her own projects and interests. An important distinction can be drawn here between first-order and second-order impartiality (Barry 1995). First-order impartiality is that displayed by an agent in ordinary choice situations -- choosing how to spend one's day, who to spend time with, and so forth. Second-order impartiality, by contrast, operates only in a certain, special sort of context: contexts in which the rules, principles and institutions which govern first-order behavior are evaluated and selected. Thus a moral rule granting individuals complete freedom of association, and thus allowing them to display first-order partiality by spending time with whomever they please regardless of whether doing so promotes the greater social good in any particular case, might be given a second-order impartialist justification by demonstrating that such a rule would promote the impersonal good, or that it would be selected by a group of impartial persons who were choosing the moral rules that were to govern society.

The fact that deontological theories generally permit (some degree of) first-order partiality -- that is, that agents are permitted to pay special attention to their own interests, projects, and loved ones -- should not, then, be taken to imply either that the agent's interests are *objectively* more valuable than those of other persons, or that the agent is justified in viewing them as such. Rather, the deontologist will claim, it reflects the fact that it is morally legitimate (perhaps, again, because justifiable in second-order impartialist terms) for an agent to regard her own goals and interests as especially important *to her*. Thus, deontological moral systems tend to incorporate an irreducible element of agent-relativity of a sort that consequentialist theories cannot embody (Nagel 1986; McNaughton & Rawling 1992, 1993, 1998; Jollimore 2001).

The incorporation of agent-relativity of this sort into deontological theories allows such theories to escape the most straightforward versions of the claim that they demand too much of moral agents (Jollimore 2001). Nevertheless, various versions of that objection have been leveled against deontological theories. It has been claimed, for instance, that Kantianism, by insisting that only actions performed out of the motive of duty have moral worth, deligitimizes or even forbids the type of motives which typically (and perhaps necessarily) operate in the context of close personal relationships (Stocker 1976; Williams; 1981). Typically, Kantians have responded by distancing themselves from the view that *only* actions motivated by duty have value, and acknowledging instead that a commitment to duty need only function as a limiting condition, rather than as the primary source of motivation in all cases (Baron 1995). The Kantian account of moral value, of course, is not essential to deontological theories; and those theories which eschew it may well be able to avoid the demandingness objection altogether.

4.2 Impartiality and universalizability

On many deontological views, particularly Kantian ones, the significance of moral impartiality is seen as arising from the fact that a core role is given to the concept of universalizability (Gert 1998; Hare 1981; Kant 1964 [1785]; Kohlberg 1979). The requirement that moral judgments be universalizable is, roughly, the requirement that such judgments be independent of any particular point of view. Thus, an agent who judges that *A* ought morally to do *X* in situation *S* ought to be willing to endorse the same judgment whether she herself happens to be *A*, or some other individual involved in the situation (someone who, perhaps, will be directly affected by *A*'s actions), or an entirely neutral observer. Her particular identity is completely irrelevant in the determination of the correctness or appropriateness of the judgment.

Universalizability, thus formulated, does imply at least one sort of impartiality: an agent whose judgments are universalizable will be morally consistent, in the sense that she will judge her own actions by the same standards she applies to others. Such an agent will not make an exception of herself by allowing herself to break a rule she regards as binding for others, or to perform any other action which she would not accept if performed by another agent. Impartiality of this sort, however, does not necessarily imply any sort of impartiality with respect to other individuals' interests, rights, or claims. On a minimally demanding interpretation of the universalizability requirement, the judgments made by a person whose conception of the good was intrinsically racist -- that is, a person who held that the well-being of members of some one particular race mattered more (or less), objectively speaking, than the well-being of members of other races -- could very well turn out to be universalizable, so long as the racist held that his judgments were

objectively correct, and so ought to be assented to by all individuals -- including those individuals who would be disadvantaged by the general adoption of those views (cf. Gewirth 1978, p. 164; Gert 1998, Chapter 6; Wiggins 1978; Williams 1985, p. 115).

However, the conclusion that the racist's judgments are universalizable presupposes a very minimal account of what universalizability requires. On this account, it requires only that an agent be sincerely committed to the objectivity of his judgments, in the sense that he views them (from his current perspective) as correct from all perspectives, and thus as calling for everyone's assent (whether or not that assent is actually given.) There are two ways of making the universalizability requirement more demanding. The first is to appeal to certain counterfactual claims about what the agent *would* endorse if he actually *did* occupy various perspectives. On this view, a particular judgment by *A* is universalizable if and only if *A* endorses that judgment from his current perspective, *and would endorse the same judgment from any other perspective*. Given this understanding of universalizability, it is much less likely -- indeed, extraordinarily unlikely -- that racist views will turn out to be universalizable; for it is not generally true of individuals that they would endorse the view "The well-being of members of race *R* matters less than the well-being of members of other races" if they themselves were members of race *R*. However, such a view may well require too much, for there are few if any moral judgments or principles that would be endorsed from *every* perspective any given agent might occupy.

A different approach to universalizability eschews the appeal to psychological facts altogether, and holds that whether or not a particular judgment is universalizable is a logical fact rather than a psychological one. Kant's categorical imperative test, for example, holds that universalizability is the distinguishing feature of correct moral judgments, and that a judgment is universalizable if and only if it can, without contradiction, be willed as a universal practical law (Kant 1964 [1785]). Since the test hinges on whether the willing of a judgment as a universal law results in a *contradiction*, it follows that whether or not a judgment *is* universalizable in this way is a matter of practical reason, and does not depend on which particular individual's will happens to be involved.

The types of impartiality implied by both of these more demanding versions of the universalizability requirement are likely to be considerably more substantial than the formal consistency required by the minimal version. Kant, for instance, seems to hold that universalizability implies a certain level of altruism or charity, in the form of the imperfect duties we owe towards other individuals. There are problems, however, with Kant's argument for this. In particular, it is not clear just how the universal willing of a maxim such as "When others are in need of help, I always ignore their needs" give rise to any sort of *contradiction*. It is true, of course, that, were we actually in a position to choose the universal maxims on which all rational persons would act, this would be a poor choice, for we might someday be in need of assistance from another. But to say that the willing of this maxim as a universal law would be *imprudent* is not to say that doing so is *contradictory*. Moreover, as David Wiggins (1978) points out, certain other actions that seem as if they ought to be morally permissible -- the act, for instance, of releasing a debtor from his debt out of generosity -- have maxims that seem to fail the universalizability test so conceived. These examples may point to a general problem with the attempt to derive impartiality from universalizability: whereas the latter, at least on a Kantian interpretation, is a formal property of moral judgments, moral impartiality, as we have seen, is a substantive rather than a formal concept. (See

Herman 1993 and Korsgaard 1996 for attempts to respond to these problems.)

It should be mentioned that some moral theorists have attempted to derive various versions of consequentialist impartiality more or less directly from the universalizability requirement (Hare 1981, Pettit 2000; see also Harsanyi 1982). However, the claim that a conception of impartiality that is not only substantive but also extraordinarily demanding can be derived from a requirement which, as just pointed out, is essentially a formal one, continues to strike a majority of moral philosophers as dubious.

4.3 Contractualist models of deontological impartiality

The requirement that moral judgements be universalizable seems to reflect two fundamental moral insights: first, that morality is objective, and not simply a matter of personal opinion or expression of interest and desire; and second, that from the standpoint of morality, each person matters just as much as, and no more than, any other person. The *contractualis*t approach to moral theorizing provides one method of giving expression to these fundamental ideas about morality.

Contractualism borrows from the social contract tradition the idea that morality may be viewed as the result of an agreement between those who are to be bound by its dictates. Two variants of this approach can be distinguished. The former, sometimes referred to as *contractarianism*, identifies the participants in the bargaining process with actual individuals, and thus is broadly historical. The latter approach, by contrast, appeals to what agents *would* choose under various, quite possibly unrealizable conditions, and is thus *hypothetical* rather than historical. It is the latter approach that will concern us here.

The hypothetical contractualist model, then, regards moral principles as the result of a bargaining process among a group of agents, subject to certain restrictions that are specified so as to guarantee that the chosen principles will meet the demands of second-order impartiality. The most famous example of this approach is John Rawls' "veil of ignorance", as described in (Rawls 1971). According to Rawls, the principles of a just society are those that would be chosen by self-interested rational agents in the "original position" -- a position in which agents possess broad knowledge about human history and the nature of the world they live in, but are denied specific information regarding their own particular identities or prospects in the society in question, the nature of that society, and, crucially, the nature of their own particular conception of the good. Since nobody knows who they will be or what social position they will occupy, there is no opportunity for anyone in an advantaged position to take advantage of that position in order to force a less privileged party to concede to an otherwise unacceptable outcome. It is this fact that allows Rawls to claim that principles chosen under the veil of ignorance are guaranteed to be impartially acceptable to all -- and thus, guaranteed not to be unjust.

It should be noted that Rawls does not intend that morality in its entirely be derived from the original position. Rather, the function of the original position is limited to the choice of the most general principles of social justice in a well-ordered society (Rawls 1971, section 2; 2001, section 12). Nevertheless, Rawls' mechanism is intended to draw the broad outlines of what many see as the most important part of morality: its public or political aspect. By viewing political morality as the result of an agreement between

contractors limited by the strictures of the veil of ignorance, Rawls intends to develop a political philosophy that reflects his commitment to the idea of liberal neutrality: the idea, that is, that each person has a private right to her own conception of the good, and that particular conceptions of the good therefore ought not to be legislatively instituted, nor legislated against

An especially difficult task attending a project of this sort is that of determining what shape this political morality will take -- that is, determining which principles would be chosen by agents in the original position. On Rawls' account, the contractors settle on principles that guaranteed as much liberty as possible for all and, within the limits set by this guarantee, a roughly egalitarian distribution of goods in which inequalities are allowed only if they are to the benefit of the worst off (Rawls 1971, section 11; 2001, Part II). The claim that such principles would recognize all persons as equals -- and thus, their claim to reflect the demands of moral impartiality -- is supported by several considerations, of which three are perhaps most significant: first, that all persons are guaranteed equal (and substantial) civil liberties; second, that the resulting allocation of resources is broadly egalitarian, and in particular, ensures, so far as is possible, that the fundamental needs of all persons are met; and third, that since the only inequalities that are permitted are those that would benefit the least advantaged, it can presumably be assumed that the least advantaged would give their assent to the existence of such inequalities (they would not, even if they could, veto the system.)

In Rawls' scheme, the function of the veil of ignorance is necessary to prevent rational self-interested persons from using their knowledge of their own positions to win unfair advantages over others. An alternative approach abandons both the veil of ignorance and the assumption that the bargaining parties are primarily self-interested. This is the strategy favored by T.M. Scanlon, whose contractors are motivated not by self-interest but by "the desire for reasonable agreement" (Scanlon 1982, p. 115 n. 10; see also Scanlon 1978, 1998; Barry 1995). On the resulting account of moral permissibility, "an act is wrong if its performance under the circumstances would be disallowed by any system of rules for the general regulation of behavior which no one could reasonably reject as a basis for informed, unforced general agreement." (Scanlon, 1982, p. 110) The requirement of impartiality is captured here by the basic fact that the question is whether *everyone* who is to live under the selected rules can reasonably accept them. As in Rawls' theory, however, the principles of second-order impartiality accepted at the contract level allow for considerable first-order partiality at the level of agent-choice.

Harsanyi (1977) argues that a version of utilitarianism can be defended on the basis of an "equiprobability model," according to which an agent ought to choose between social systems "under the assumption that, in either system, he would have the same probability of occupying any one of the available social positions" (Harsanyi 1982, p. 45; cf. Hare 1981). Gert (1998) argues for a list of moral rules which "all impartial rational persons would favor including […] as part of the moral system" (p. 158). Gauthier (1986) defends a contemporary version of contractarianism.

5. Objections to traditional conceptions of moral impartiality

Traditional conceptions of impartiality such as those we have been discussing face a variety of objections. Many of these objections focus on the claim that such conceptions take insufficient account of the nature of the moral agent and of the pragmatics of the situations in which impartial decisions are actually made. Along these lines, some objectors claim that traditional conceptions set the bar too high, demanding superhuman abilities or cognitive efforts from moral agents. Others, meanwhile, concentrate on the fact that the traditional conceptions tend to identify impartiality with an unemotional, dispassionate disposition, or with impersonal bureaucratic institutions; or, more generally, to abstract away from the particular natures of the contesting parties in developing an account of impartial decision-making procedures.

The first charge -- that impartiality, as conceived by traditional ethical theories, makes extraordinary and unreasonable cognitive demands on moral agents -- must be distinguished from the objection to consequentialist impartiality considered earlier, which claimed that the *sacrifices* demanded by consequentialist impartiality were unreasonable and excessive. The objection now being considered is not that impartiality asks the agent to give up too much, but rather that the cognitive feats demanded by these moral theories will exceed the capacity of the typical moral agent. Indeed, one popular version of this objection alleges that an agent will require an unreasonable amount of knowledge or cognitive ability simply to be able to identify what the demands of impartiality *are* (Friedman 1989; Walker 1991). Given the conception of the impartial point of view as a "God's eye" point of view, for example (Baier 1958), it seems questionable whether it is ever reasonable to expect a human moral agent to be able to occupy such a perspective. God, quite obviously, possesses far more knowledge than does any human being; moreover, God's point of view is both objective and impersonal in ways that an individual human's perspective cannot be. . (As Margaret Urban Walker points out, it is often said that human beings have to live with their decisions, but it sounds very odd to say that of God (Walker 1991, p. 765).) Similar remarks apply to the conception of the impartial point of view as "the point of view of the universe" (Sidgwick 1907), to Hare's conception of the ideal moral agent as a so-called "archangel" (Hare, 1981), and, Walker claims, to Firth's conception of the ideal impartial observer (Firth, 1952.) Similarly, Marilyn Friedman points out that even if a person did manage to occupy such a point of view for a period of time-- supposing such a thing to be possible -- there would be no way to confirm that she had successfully done so: standard conceptions of impartiality, she claims, prescribe "methods of normative thinking [which] represent psychological and epistemic feats, the achievement of which we have no independent way to confirm" (Friedman 1991, p. 645).

The second objection finds fault with the traditional tendency to define impartiality in negative or abstract terms -- in terms, that is, of which elements must be *absent* from the psychology of the agent, or which we must *pretend* are absent in the process of idealization. M.C. Henberg, for instance, claims that most if not all procedural accounts of impartiality confuse it with distinterest or impersonality, and thus, ultimately, with indifference. (It should be noted that many impartialists are quite explicit about the link between morality, impartiality, and the lack of emotion; Baier (1958), for instance, writes that "the moral point of view [is] that of an independent, unbiased, impartial, objective, dispassionate, disinterested observer" (p. 201; see also Firth 1952).) Similarly, Richard Brandt argues that it is a mistake to define moral impartiality with reference to an ideal observer who is defined as (among other things) distinterested; for after all, "it is not clear that a purely disinterested being would support a moral system at all" (Brandt

1979, p. 227). While Brandt's complaint is particularly directed at the ideal observer theory of (Firth 1952), this objection seems to apply much more broadly; it is obvious, for instance, that Rawls's veil of ignorance is designed precisely to prevent the contractors from acting in an interested manner.

The problem is not only that impersonal persons of this sort are likely to suffer from massive indifference, but also that there is alleged to be a conceptual difficulty with the very idea of conceiving impartiality in such terms. An abstract or impersonal evaluator, it is argued, could not possibly make reliable judgments about substantive moral matters (whether or not he was motivated to), since he would be unable to appreciate the particular concerns of the contesting parties. Both of these difficulties -- the motivational and the cognitive -- are well expressed by Iris Marion Young, who rejects altogether the idea that morality is primarily a matter of impartiality:

> The ideal of impartiality is an idealist fiction. It is impossible to adopt an unsituated point of view, and if a point of view is situated, it cannot stand apart from and understand all points of view. It is impossible to reason about substantive moral issues without understanding their substance, which always presupposes some particular social and historical context; and one has no motive for making moral judgments and resolving moral dilemmas unless the outcome matters, unless one has a particular and passionate interest in the outcome […] when class, race, ethnicity, gender, sexuality, and age define different social locations, one subject cannot fully empathize with another in a different social location, adopt her point of view; if that were possible then the social locations would not be different. (Young 1990, pp. 104-5; cf. Benhabib 1987, p. 90)

A similar complaint against Rawls is lodged by Shane O'Neill, who writes that Rawls's isolation of political from personal morality results in a theory in which certain contentious moral issues are resolved essentially by fiat: since the moral views of certain contesting parties are defined as personal rather than political matters, they have no chance of effectively defending them in the public sphere (O'Neill 1997, Chapter 1).

If genuine impartiality is an illusion, as Young alleges, then impartialists may be suspected in smuggling in their own substantive moral positions and biases under the guise of neutrality. Rawls' use of the veil of ignorance, for example, has been criticized by Thomas Nagel and others on the basis that, by requiring that agents lack knowledge of their conceptions of the good (a necessary stipulation of the bargainers are to achieve a consensus), the veil of ignorance excludes from the original position information that is morally relevant, and indeed may put some of the bargainers at a disadvantage. "The original position," Nagel writes, "seems to presuppose not just a neutral theory of the good, but a liberal, individualistic conception according to which the best that can be wished for someone is the unimpeded pursuit of his own path, provided it does not interfere with the rights of others" (Nagel 1973; see also. Teitelman 1972; Schwartz 1973; Sandel 1982; Benhabib 1987). Such a conception, it is held, clearly does favor some conceptions of the good over others: in particular, atomic, individualistic conceptions focusing on personal fulfillment (constituted, perhaps, through the acquisition of consumer goods) are privileged over more communal or social ideals that focus on solidarity and mutual interaction between persons (Sandel 1982; cf. O'Neill 1997, Chapter 1).

Feminist critics have paid particular attention to the ways in which liberal conceptions of neutrality and impartiality presuppose and reinforce traditional male-dominated, individualistic approaches to moral theory, and in doing so reinforce the social status quo (Gilligan 1982; Noddings 1984; Benhabib 1987; Young 1990). As Benhabib has pointed out, "Universalistic moral theories in the Western tradition from Hobbes to Rawls are *substitutionalist*, in the sense that the universalism they defend is defined surreptitiously by identifying the experiences of a specific group of subjects as the paradigmatic case of the human as such. These subjects are invariably white, male adults who are propertied or at least professional." (Benhabib 1987, p. 81) As a result, the dominant social positions of such parties tend to be protected and even enhanced in the social and political theories resulting from such allegedly neutral liberal theories.

Such criticisms need not lead us to reject the idea of a moral role for impartiality altogether. Rather, many of the critics considered have thought that there were better models available for understanding impartiality. Many of these models are guided by the thought that the impartial observers, actors or paradigm agents need to be humanized in various ways: by allowing them to retain their conceptions of the good (to a certain extent at least) behind the veil of ignorance; by abandoning totalizing urge that leads us to think of all impartial decisions as being made by essentially one, perfectly abstract agent; and by reducing the cognitive requirements for such agents. Thus, rather than picturing impartial judgments as being made by a single person who is both omniscient and entirely disinterested, we might think of them as the result of a dialogical process between a group of quite distinct participants -- a process that is likely to involve considerably more conflict than the smooth procedure envisioned by Rawls. The general challenge facing such accounts, of course, is obvious: such a picture carried to its logical extreme would simply be identical with the actual world, in which various groups contend with one another in defense of their interests and conceptions of the good; and it is, of course, a salient feature of the actual world that agreement is extremely hard to reach. Thus, it may be worried that while humanizing models of the sort proposed will be able to avoid the difficulties that tend to plague liberal theorists who conceive of impartiality as abstraction, they will only do so by abandoning the primary attraction of such theories: their ability to derive order out of social chaos. Whether a compromise can be found that avoids both horns of this dilemma remains to be seen.

6. The partialist-impartialist debate

Although many people continue to speak of a ‘partialist vs. impartialist debate,’ it should by now be clear that neither ‘partialism’ nor ‘impartialism’ unambiguously denote any single moral position; at best, they designate two poles of a continuum, one of which attributes no moral significance to the demands of (any sort of) impartiality, the other of which sees morality as exhausted by (some version of) impartiality. While a somewhat general distinction can be usefully maintained, it is misleading to think of the partialist-impartialist debate as a dispute between two clearly defined, and clearly opposed, camps (Deigh 1991; Barry 1995, pp. 191-5).

Thus, any general claim beginning with the words ‘partialists (or impartialists) think that …’ is bound to

be both misleading and contentious. In particular, there is good reason to be wary of objections to impartialism which claim that all impartialists endorse extreme moral demands, or that they require that practical reasoning be completely expunged of every vestige of the partial. It is true, of course, that at least some impartialists, such as Godwin, have endorsed such claims. But many do not. Deontologists, as we have seen, hold impartiality to be a deep and significant element of morality, but they also tend to allow for a considerable degree of first-order partiality. And even many consequentialists are prepared to admit the legitimacy of partial reasoning in some contexts, if only on an instrumental basis. It is useful, then, to draw a distinction between two sorts of impartialist moral theory. Impartialist theories which require all agents to display first-order impartiality at all times (Godwin's, for example) might be referred to as *strict impartialist theories.* Impartialist theories which allow for some first-order partiality, but which nevertheless insist that all such behavior be justified in second-order impartialist terms, might be referred to as *fundamentally impartialist* moral theories. The class of fundamentally impartial theories will include not only contractualist, Kantian, and rule consequentialist theories, but also certain act consequentialist theories (e.g. Railton 1986) which allow the practice of first-order partiality as a means of promoting the impersonal good. Such theories allow for partiality that is permissible, justifiable, and perhaps even admirable in moral terms. At the same time, however, they insist that all such partiality is ultimately reducible -- that is, justifiable in impartialist terms at some deeper level.

Within the partialist camp, a *strict partialist* might be defined as holding that no sort of impartiality plays any moral role whatsoever -- a logically possible, but uncommon, position. A *moderate partialist*, by contrast, would admit that impartiality of some sort plays a moral role, but deny that this role encompasses, or grounds, all of morality; in particular, such a figure would be committed to the existence, in some contexts at least, of irreducible morally admirable partiality. A virtue theorist, for instance, might make a significant place for impartiality by selecting it as one of the virtues; but a virtue of this sort would presumably have to compete with other deeply partialist virtues such as loyalty, which would override impartiality in at least some contexts.

To the extent that a deep issue between partialists and impartialists can be identified, it is presumably the question of whether (irreducible) morally admirable partiality does indeed exist; and it is along this line of dispute that the debate seems likeliest to continue. (Whether this debate is identical to the so-called 'justice-care' debate, as contended in Cannold, *et al* (1995), is questionable, though it is undeniable that there are important parallels.) However, this way of classifying the disputants, and of characterizing the issue itself, is meant to be suggestive rather than definitive. The fact remains that there are many types of partialist theories, and many types of impartialist ones, and that continuing to speak of the 'partialist-impartialist debate' in loose and imprecise terms is more likely to obscure than to illuminate.

Equality

This article is concerned with social and political equality. In its prescriptive usage, ‘equality’ is a loaded and ‘highly contested’ concept. On account of its normally positive connotation, it has a rhetorical power rendering it suitable as a political slogan (Westen 1990). At least since the French Revolution, equality has served as one of the leading ideals of the body politic; in this respect, it is at present probably the most controversial of the great social ideals. There is controversy concerning the precise notion of equality, the relation of justice and equality (the principles of equality), the material requirements and measure of the ideal of equality (equality of what?), the extension of equality (equality among whom?), and its status within a comprehensive (liberal) theory of justice (the value of equality). Each of these five issues will be discussed by turn in the present article.

1. Defining the Concept

‘Equality’ is a contested concept: "People who praise it or disparage it disagree about what they are praising or disparaging" (Dworkin 2000, p. 2). Our first task is therefore to provide a clear definition of equality in the face of widespread misconceptions about its meaning as a political idea.

The terms "equality" (Gr. isotes, Lat. aequitas, aequalitas, Fr. égalité, Ger. Gleichheit), "equal," and "equally" signify a qualitative relationship. ‘Equality’ (or ‘equal’) signifies correspondence between a group of different objects, persons, processes or circumstances that have the same qualities in at least one respect, but not all respects, i.e., regarding one specific feature, with differences in other features. ‘Equality’ needs to thus be distinguished from ‘identity’ -- this concept signifying that one and the same

object corresponds to itself in all its features: an object that can be referred to through various individual terms, proper names, or descriptions. For the same reason, it needs to be distinguished from ‘similarity’ -- the concept of merely approximate correspondence (Dann 1975, p. 997; Menne 1962, p. 44 ff.; Westen 1990, pp. 39, 120). Thus, to say e.g. that men are equal is not to say that they are identical. Equality rather implies similarity but not ‘sameness.’

In distinction to numerical identity, a judgment of equality presumes a difference between the things being compared. According to this definition, the notion of ‘complete’ or ‘absolute’ equality is self-contradictory. Two non-identical objects are never completely equal; they are different at least in their spatiotemporal location. If things do not differ they should not be called ‘equal,’ but rather, more precisely, ‘identical,’ as e.g., the morning and evening star. Here usage might vary. Some authors do consider absolute qualitative equality admissible as a borderline concept (Tugendhat & Wolf 1983, p. 170).

‘Equality’ can be used in the very same sense both to describe and prescribe, as with "thin": "you are thin" and "you are too thin." The approach taken to defining the standard of comparison for both descriptive and prescriptive assertions of the concept of equality is very important (Oppenheim 1970). In the case of *descriptive* use of equality, the common standard is itself descriptive, e.g. two people weigh the same. A *prescriptive* use of equality is present when a prescriptive standard is applied, i.e., a norm or rule, e.g. people ought to be equal before the law. The standards grounding prescriptive assertions of equality contain at least two components. On the one hand, there is a descriptive component, since the assertions need to contain descriptive criteria, in order to identify those people to which the rule or norm applies. The question of this identification -- who belongs to which category? -- may itself be normative, e.g. to whom do the U.S. laws apply? On the other hand, the comparative standards contain something normative -- a moral or legal rule, in the example, the U.S. laws -- specifying how those falling under the norm are to be treated. Such a rule constitutes the prescriptive component (Westen 1990, chap. 3). Sociological and economic analyses of (in-)equality mainly pose the questions of how inequalities can be determined and measured and what their causes and effects are. In contrast, social and political philosophy is in general concerned mainly with the following questions: *what kind* of equality, if any, should be offered, and to *whom* and *when*? Such is the case in this article as well.

‘Equality’ and ‘equal’ are incomplete predicates that necessarily generate one question: equal in what respect? (Rae 1980, p. 132 f.) Equality essentially consists of a tripartite relation between two (or several) objects or persons and one (or several) qualities. Two objects a and b are equal in a certain respect if, in that respect, they fall under the same general terminus. ‘Equality’ denotes the relation between the objects that are compared. Every comparison presumes a *tertium comparationis*, a concrete attribute defining the respect in which the equality applies -- equality thus referring to a common sharing of this comparison-determining attribute. This relevant comparative standard represents a ‘variable’ (or ‘index’) of the concept of equality that needs to be specified in each particular case (Westen 1990, p. 10); differing conceptions of equality here emerge from one or another descriptive or normative moral standard. There is another source of diversity as well: As Temkin (1986, 1993) argues, various different standards might be used to measure inequality, with the respect in which people are compared remaining constant. The difference between a general concept and different specific conceptions (Rawls 1971, p. 21 f.) of equality

may explain why according to various authors producing ‘equality’ has no unified meaning -- or even is devoid of meaning. (Rae 1981, p. 127 f., 132 f.)

For this reason, it helps to think of the idea of equality or for that matter inequality, understood as an issue of social justice, not as a single principle, but as a complex group of principles forming the basic core of today's egalitarianism. Depending on which procedural principle one adopts, contrary answers are forthcoming. Both equality and inequality are complex and multifaceted concepts (Temkin 1993, chap. 2). In any real historical context, it is clear that no single notion of equality can sweep the field. (Rae 1981, p. 132) Many egalitarians concede that much of our discussion of the concept is vague and theoretical. But they believe that there is also a common underlying strain of important moral concerns implicit in it (Williams 1973). Above all it serves to remind us of our common humanity, despite various differences (cf. 2.3. below). In this sense, egalitarians tend to think of egalitarianism as a single coherent normative doctrine -- but one in any case embracing a variety of principles. Following the introduction of different principles and theories of equality, I will return in the last section of this article to the question how best to define egalitarianism and the value of equality.

2. Principles of Equality and Justice

Equality in its prescriptive usage has, of course, a close connection with morality and justice in general and distributive justice in particular. From antiquity onward, equality has been considered a constitutive feature of justice. (On the history of the concept, cf. Albernethy 1959, Benn 1967, Brown 1988, Dann 1975, Thomson 1949.) Throughout history, people and emancipatory movements use the language of justice to pillory certain inequalities. But what exactly is the connection between equality and justice, i.e., what kind of role does equality play in a theory of justice? The role and correct account of equality, understood as an issue of social justice, is itself a difficult philosophical issue. To clarify this, philosophers have defended a variety of principles and conceptions of equality, many of which are mentioned in the following discussion. This section introduces four well known principles of equality, ranging from highly general and uncontroversial to more specific and controversial. The next section reviews various conceptions of the ‘currency’ of equality. Different interpretations of the role of equality in a theory of justice emerge according to which of the four following principles and which measure has been adopted.

Through its connection with justice, equality, like justice itself, has different *justitianda*, i.e., objects the term ‘just’ or ‘equal’ or their opposites can be applied to. These are mainly actions, persons, social institutions, and circumstances (e.g. distributions). These objects of justice stand in an internal connection and order that can here only be hinted at. The predicates "just" or "unjust" are only applicable when *voluntary* actions implying responsibility are in question. Justice is hence primarily related to individual actions. Individual persons are the primary bearer of responsibilities (ethical individualism). Persons have to take responsibility for their individual actions and for circumstances they could change through such actions or omissions. Although people have responsibility for both their actions and circumstances, there is a moral difference between the two *justitianda*, i.e., an injustice due to unjust treatment through an individual or collective action and an injustice due to a failure to correct unjust circumstances (cf. 3.1.v.

below). The responsibility people have to treat individuals and groups they affect in a morally appropriate and, in particular, even-handed way has hence a certain priority over their moral duty to turn circumstances into just ones through some kind of equalization. Establishing justice of circumstances (ubiquitously and simultaneously) is beyond any given individual's capacities. Hence one has to rely on collective actions. In order to meet this moral duty, a basic order guaranteeing just circumstances must be justly created. This is an essential argument of justice in favor of establishing social institutions and fundamental state structures for political communities; with the help of such institutions and structures, individuals can collectively fulfill their responsibility in the best possible manner. If circumstances can be rightly judged to be unjust, all persons have the responsibility and moral duty, both individually and collectively, to change the pertinent circumstances or distributive schemes into just ones. In the following sections, the objects of equality may vary from topic to topic. However, as indicated, there is a close relationship between the objects. The next three principles of equality hold generally and primarily for all actions and treatment of others and for resulting circumstances. From the fourth principle onward, i.e., starting with the presumption of equality, this article is mainly concerned with distributive justice and the evaluation of distribution.

2.1 Formal Equality

When two persons have equal status in at least one normatively relevant respect, they must be treated equally with regard to this respect.This is the generally accepted *formal* equality principle that Aristotle formulated in reference to Plato: "treat like cases as like" (Aristotle, *Nicomachean Ethics*, V.3. 1131a10-b15; *Politics*, III.9.1280 a8-15, III. 12. 1282b18-23). Of course the crucial question is which respects are normatively relevant and which are not. Some authors see this formal principle of equality as a specific application of a rule of rationality: it is irrational, because inconsistent, to treat equal cases unequally without sufficient reasons (Berlin 1955-56). But most authors instead stress that what is here at stake is a moral principle of justice, basically corresponding with acknowledgment of the impartial and universalizable nature of moral judgments. Namely, the postulate of formal equality demands more than consistency with one's subjective preferences. What is more important is possible justification vis-à-vis others of the equal or unequal treatment in question -- and this on the sole basis of a situation's objective features.

2.2 Proportional Equality

According to Aristotle, there are two kinds of equality, numerical and proportional (Aristotle, *Nicomachean Ethics*, 1130b-1132b; cf. Plato, *Laws*, VI.757b-c). A form of treatment of others or as a result of it a distribution is equal *numerically* when it treats all persons as indistinguishable, thus treating them identically or granting them the same quantity of a good per capita. That is not always just. In contrast, a form of treatment of others or distribution is *proportional* or relatively equal when it treats all relevant persons in relation to their due. Just *numerical* equality is a special case of proportional equality. Numerical equality is only just under special circumstances, viz. when persons are equal in the relevant respects so that the relevant proportions are equal. Proportional equality further specifies formal equality; it is the more precise and detailed, hence actually the more comprehensive formulation of formal equality.

It indicates what produces an adequate equality.

Proportional equality in the treatment and distribution of goods to persons involves at least the following concepts or variables: Two or more persons (P_1, P_2) and two or more allocations of goods to persons (*G*) and *X* and *Y* as the quantity in which individuals have the relevant normative quality *E*. This can be represented as an equation with fractions or as a ratio. If P_1 has *E* in the amount of *X* and if P_2 has *E* in the amount *Y*, then *P*1 is due *G* in the amount of X' and P_2 is due *G* in the amount of Y', so that the ratio $X/Y = X'/Y'$ is valid. (N.B. For the formula to be usable, the potentially great variety of factors involved have to be both quantifiable in principle and commensurable, i.e., capable of synthesis into an aggregate value.)

When factors speak for unequal treatment or distribution, because the persons are unequal in relevant respects, the treatment or distribution proportional to these factors is just. Unequal claims to treatment or distribution must be considered proportionally: that is the prerequisite for persons being considered equally.

This principle can also be incorporated into hierarchical, inegalitarian theories. It indicates that equal output is demanded with equal input. Aristocrats, perfectionists, and meritocrats all believe that persons should be assessed according to their differing deserts, understood by them in the broad sense of fulfillment of some relevant criterion. And they believe that reward and punishment, benefits and burdens, should be proportional to such deserts. Since this definition leaves open who is due what, there can be great inequality when it comes to presumed fundamental (natural) rights, deserts, and worth -- and such inequality is apparent in both Plato and Aristotle.

Aristotle's idea of justice as proportional equality contains a fundamental insight. The idea offers a framework for a rational argument between egalitarian and non-egalitarian ideas of justice, its focal point being the question of the basis for an adequate equality (Hinsch, forthcoming 2002). Both sides accept justice as proportional equality. Aristotle's analysis makes clear that the argument involves the features deciding whether two persons are to be considered equal or unequal in a distributive context.

On the formal level of pure conceptual explication, justice and equality are linked through these principles of formal and proportional justice. Justice cannot be explained without these equality principles; the equality principles only receive their normative significance in their role as principles of justice.

Formal and proportional equality is simply a conceptual schema. It needs to be made precise -- i.e., its open variables need to be filled out. The formal postulate remains quite empty as long as it remains unclear when or through what features two or more persons or cases should be considered equal. All debates over the proper conception of justice, i.e., over who is due what, can be understood as controversies over the question of which cases are equal and which unequal (Aristotle, *Politics*, 1282b 22). For this reason equality theorists are correct in stressing that the claim that persons are owed equality becomes informative only when one is told -- what *kind* of equality they are owed (Nagel 1979; Rae

1981; Sen 1992, p. 13). Actually, every normative theory implies a certain notion of equality. In order to outline their position, egalitarians must thus take account of a specific (egalitarian) conception of equality. To do so, they need to identify substantive principles of equality, discussed below.

2.3 Moral Equality

Until the eighteenth century, it was assumed that human beings are unequal by nature -- i.e., that there was a natural human hierarchy. This postulate collapsed with the advent of the idea of natural right and its assumption of an equality of natural order among all human beings. Against Plato and Aristotle, the classical formula for justice according to which an action is just when it offers each individual his or her due took on a substantively egalitarian meaning in the course of time, viz. everyone deserved the same dignity and the same respect. This is now the widely held conception of substantive, universal, moral equality. It developed among the Stoics, who emphasized the natural equality of all rational beings, and in early New Testament Christianity, which elevated the equality of human beings before God to a principle: one to be sure not always adhered to later by the Christian church. This important idea was also taken up both in the Talmud and in Islam, where it was grounded in both Greek and Hebraic elements in both systems. In the modern period, starting in the seventeenth century, the dominant idea was of natural equality in the tradition of natural law and social contract theory. Hobbes (1651) postulated that in their natural condition, individuals possess equal rights, because over time they have the same capacity to do each other harm. Locke (1690) argued that all human beings have the same natural right to both (self-)ownership and freedom. Rousseau (1755) declared social inequality to be a virtually primeval decline of the human race from natural equality in a harmonious state of nature: a decline catalyzed by the human urge for perfection, property and possessions (Dahrendorf 1962). For Rousseau (1755, 1762), the resulting inequality and rule of violence can only be overcome by tying unfettered subjectivity to a common civil existence and popular sovereignty. In Kant's moral philosophy (1785), the categorical imperative formulates the equality postulate of universal human worth. His transcendental and philosophical reflections on autonomy and self-legislation lead to a recognition of the same freedom for all rational beings as the sole principle of human rights (Kant 1797, p. 230). Such Enlightenment ideas stimulated the great modern social movements and revolutions, and were taken up in modern constitutions and declarations of human rights. During the French Revolution, equality -- along with freedom and fraternity -- became a basis of the *Déclaration des droits de l´homme et du citoyen* of 1789.

The principle of equal dignity and respect is now accepted as a minimum standard throughout mainstream Western culture. Some misunderstandings regarding moral equality need to be clarified. To say that men are equal is not to say they are identical. The postulate of equality implies that underneath apparent differences, certain recognizable entities or units exist that, by dint of being units, can be said to be ‘equal.’ (Thomson 1949, p. 4). Fundamental equality means that persons are alike in important relevant and specified respects alone, and not that they are all generally the same or can be treated in the same way (Nagel 1991). In a now commonly posed distinction, stemming from Dworkin (1977, p. 370), moral equality can be understood as prescribing treatment of persons as equals, i.e., with equal concern and respect, and not the often implausible principle of treating persons equally. This fundamental idea of equal respect for all persons and of the equal worth or equal dignity of all human beings (Vlastos 1962) is accepted as a minimal standard by all leading schools of modern Western political and moral culture. Any

political theory abandoning this notion of equality will not be found plausible today. In a period in which metaphysical, religious and traditional views have lost their general plausibility (Habermas 1983, p. 53, 1992, pp. 39-44), it appears impossible to peacefully reach a general agreement on common political aims without accepting that persons must be treated as equals. As a result, moral equality constitutes the 'egalitarian plateau' for all contemporary political theories (Kymlicka 1990, p.5). To recognize that human beings are all equally individual does not mean having to treat them uniformly in any respects other than those in which they clearly have a moral claim to be treated alike. Disputes arise, of course, concerning what these claims amount to and how they should be resolved. That is the crux of the problem to which I now turn.

Since "treatment as an equal" is a shared moral standard in contemporary theory, present-day philosophical debates are concerned with the kind of equal treatment normatively required when we mutually consider ourselves persons with equal dignity. The principle of moral equality is too abstract and needs to be made concrete if we are to arrive at a clear moral standard. Nevertheless, no conception of just equality can be deduced from the notion of moral equality. Rather, we find competing philosophical conceptions of equal treatment serving as interpretations of moral equality. These need to be assessed according to their degree of fidelity to the deeper ideal of moral equality (Kymlicka 1990, p. 44). With this we finally switch the object of equality from treatment to the fair distribution of goods and ills or bads.

2.4 Presumption of Equality

Many conceptions of equality operate along procedural lines involving a *presumption of equality*. While more materially concrete, ethical approaches, as described in the next section below, are concerned with distributive criteria; the presumption of equality, in contrast, is a formal, procedural principle of construction located on a higher formal and argumentative level. What is here at stake is the question of the principle with which a material conception of justice should be constructed -- particularly once the above-described approaches turn out inadequate. The presumption of equality is a prima facie principle of equal distribution for all goods politically suited for the process of public distribution. In the domain of political justice, all members of a given community, taken together as a collective body, have to decide centrally on the fair distribution of social goods, as well as on the distribution's fair realization. Any claim to a particular distribution, including any existing distributive scheme, has to be impartially justified, i.e., no ownership will be recognized without justification. Applied to this political domain, the presumption of equality requires that everyone, regardless of differences, should get an equal share in the distribution unless certain types of differences are relevant and justify, through universally acceptable reasons, unequal distribution. (With different terms and arguments, this principle is conceived as a presumption by Benn & Peters (1959, 111) and by Bedau (1967, 19); as a relevant reasons approach by Williams (1973); as a conception of symmetry by. Tugendhat (1993, 374; 1997, chap. 3); as default option by Hinsch (2001, chap. 5); for criticism of the presumption of equality, cf. Westen (1990, chap. 10).) This presumption results in a principle of prima facie equal distribution for all distributable goods. A strict principle of equal distribution is not required, but it is morally necessary to justify impartially any unequal distribution. The burden of proof lies on the side of those who favor any form of unequal distribution.

The presumption in favor of equality can be justified by the principle of equal respect together with the requirement of universal and reciprocal justification; that requirement is linked to the morality of equal respect granting each individual equal consideration in every justification and distribution. Every sort of public, political distribution is, in this view, to be justified to all relevantly concerned persons, such that they could in principle agree. Since it is immoral to force someone to do something of which he or she does not approve, only reasons acceptable to the other person can give one the moral right to treat the person in accordance with these reasons. The impartial justification of norms rests on the reciprocity and universality of the reasons. Universal norms and rights enforced through inner or external sanctions are morally justified only if, on the one hand, they can be reciprocally justified, i.e., if one person asks no more of the other than what he or she is willing to give (reciprocity), and if, on the other hand, they are justified with respect to the interests of all concerned parties, i.e., if everyone has good reasons for accepting them and no one has a good reason for rejecting them (universality) (Forst 1994, p. 68, Scanlon 1998). In the end, only the concerned parties can themselves formulate and advocate their (true) interests. Equal respect, which we reciprocally owe to one another, thus requires respect for the autonomous decisions of each non-interchangeable individual (Wingert 1993, p. 90-96). This procedural approach to moral legitimation sees the autonomy of the individual as the standard of justification for universal rules, norms, rights etc. Only those rules can be considered legitimate to which all concerned parties can freely agree on the basis of universal, discursively applicable, commonly shared reasons. Equal consideration is thus accorded to all persons and their interests. In a public distribution anyone who claims more owes all others an adequate universal and reciprocal justification. If this cannot be provided, i.e., if there is no reason for unequal distribution that can be universally and reciprocally recognized by all (since, lets assume, all are by and large equally productive and needy), then equal distribution is the only legitimate distribution. How could it be otherwise? Any unequal distribution would mean that someone receives less, and another more. Whoever receives less can justifiably demand a reason for he or she being disadvantaged. Yet there is *ex hyphothesi* no such justification. Hence, any unequal distribution is illegitimate in this case. If no convincing reasons for unequal distribution can be brought forward, there remains only the option of equal distribution. Equal distribution is therefore not merely one among many alternatives, but rather the inevitable starting point that must be assumed insofar as one takes the justificatory claims of all to be of equal weight.

The presumption of equality provides an elegant procedure for constructing a theory of distributive justice. The following questions would have to be answered in order to arrive at a substantial and full principle of justice.

- What goods and burdens are to be justly distributed (or should be distributed)? Which social goods comprise the object of distributive justice?
- What are the spheres (of justice) into which these resources have to be grouped?
- Who are the recipients of distribution? Who has a prima facie claim to a fair share?
- What are the commonly cited yet in reality unjustified exceptions to equal distribution?
- Which inequalities are justified?
- Which approach, conception or theory of egalitarian distributive justice is therefore the best?

What goods and burdens are to be justly distributed (or should be distributed)? There are various opinions as to which social goods comprise the object of distributive justice. Does distributive justice apply only to those goods commonly produced, i.e., through social and economic fair cooperation, or to other goods as well, e.g. natural resources, that are not the result of common cooperation? (At present, the former approach is most apparent in Rawls (1971) and many of his adherents and critics follow Rawls in this respect.)

In the domain of public political distribution, the goods and burdens to be distributed may be divided into various categories. Such a division is essential because reasons that speak for unequal treatment in one area do not justify unequal treatment in another. What are the spheres (of justice) into which these resources have to be grouped? In order to reconstruct our understanding of contemporary liberal, democratic welfare states, four categories seem essential: 1. civil liberties, 2. opportunities for political participation, 3. social positions and opportunities, 4. economic rewards. Despite views to the contrary, liberties and opportunities are seen in this view as objects of distribution. For all four categories, the presumption of equality is the guiding principle. The results of applying the presumption to each category can then be codified as rights.

After dividing social goods into categories, we must next ask what can justify unequal treatment or unequal distribution in each category. Today the following postulates of equality are generally considered morally required.

Strict equality is called for in the legal sphere of civil freedoms, since -- putting aside limitation on freedom as punishment -- there is no justification for any exceptions. As follows from the principle of formal equality, all citizens of a society must have equal general rights and duties. These rights and duties have to be grounded in general laws applying to everyone. This is the postulate of legal equality. In addition, the postulate of equal freedom is equally valid: every person should have the same freedom to structure his or her life, and this in the most far-reaching manner possible in a peaceful and appropriate social order.

In the political sphere, the possibilities for political participation should be equally distributed. All citizens have the same claim to participation in forming public opinion, and in the distribution, control, and exercise of political power. This is the postulate -- requiring equal opportunity -- of equal political power sharing. To ensure equal opportunity, social institutions have to be designed in such a way that persons who are disadvantaged, e.g. have a stutter or a low income, have an equal chance to make their views known and to participate fully in the democratic process.

In the social sphere, social positions, equally gifted and motivated citizens must have approximately the same chances at offices and positions, independent of their economic or social class and native endowments. This is the postulate of fair equality of social opportunity. An unequal outcome has to result from equality of chances at a position, i.e., qualifications alone counting, not social background or influences of milieu.

Since the nineteenth century, the political debate has increasingly centered on the question of economic

and social inequality (this running alongside the question of -- gradually achieved -- equal rights to freedom and political participation) (Marshall 1950). The main controversy here is whether, and if so to what extent, the state should establish far-reaching equality of social conditions for all through political measures such as redistribution of income and property, tax reform, a more equal educational system, social insurance, and positive discrimination.

The equality required in the economic sphere is complex, taking account of several positions that -- each according to the presumption of equality -- justify a turn away from equality. A salient problem here is what constitutes justified exceptions to equal distribution of goods -- the main subfield in the debate over adequate conceptions of distributive equality and its currency. The following sorts of factors are usually considered eligible for justified unequal treatment: (a) need or differing natural disadvantages (e.g. disabilities); (b) existing rights or claims (e.g. private property); (c) differences in the performance of special services (e.g. desert, efforts, or sacrifices); (d) efficiency; and (e) compensation for direct and indirect or structural discrimination (e.g. affirmative action).

These factors play an essential, albeit varied, role in the following alternative egalitarian theories of distributive justice. The following theories offer different accounts of what should be equalized in the economic sphere. Most can be understood as applications of the presumption of equality (whether they explicitly acknowledge it or not); only a few (like strict equality, libertarianism, and sufficiency) are alternatives to the presumption.

3. Conceptions of Distributive Equality: Equality of What?

Every effort to interpret the concept of equality and to apply the principles of equality mentioned above demands a precise measure of the parameters of equality. We need to know the dimensions within which the striving for equality is morally relevant. What follows is a brief review of the seven most prominent conceptions of distributive equality, each offering a different answer to one question: in the field of distributive justice, what should be equalized, or what should be the parameter or "currency" of equality?

3.1 Simple Equality and Objections to Equality in General

Simple equality, meaning everyone being furnished with the same material level of goods and services, represents a strict position as far as distributive justice is concerned. It is generally rejected as untenable.

Hence with the possible exception of Barbeuf (1796), no prominent author or movement has demanded strict equality. Since egalitarianism has come to be widely associated with the demand for economic equality, and this in turn with communistic or socialistic ideas, it is important to stress that neither communism nor socialism -- despite their protest against poverty and exploitation and their demand for social security for all citizens -- calls for absolute economic equality. The orthodox Marxist view of economic equality was expounded in the *Critique of the Gotha Program* (1875). Marx here rejects the

idea of legal equality, on three grounds. In the first place, he indicates, equality draws on a merely limited number of morally relevant vantages and neglects others, thus having unequal effects; right can never be higher than the economic structure and cultural development of the society it conditions. In the second place, theories of justice have concentrated excessively on distribution instead of the basic questions of production. In the third place, a future communist society needs no law and no justice, since social conflicts will have vanished.

As an idea, *simple* equality fails because of problems that are raised in regards to equality in general. It is useful to review these problems, as they require resolution in any plausible approach to equality.

> (i) We need adequate indices for the measurement of the equality of the goods to be distributed. Through what concepts should equality and inequality be understood? It is thus clear that equality of material goods can lead to unequal satisfaction. Money constitutes a usual-index -- although an inadequate one; at the very least, equal opportunity has to be conceived in other terms.
>
> (ii) The time span needs to be indicated for realizing the desired model of equal distribution (McKerlie 1989, Sikora 1989). Should we seek to equalize the goods in question over complete individual lifetimes, or should we seek to ensure that various life segments are as equally well off as possible?
>
> (iii) Equality distorts incentives promoting achievement in the economic field, producing an inefficiency grounded in a waste of assets arising from the administrative costs of redistribution (Okun 1975). Equality and efficiency need to be placed in a balanced relation. Often, pareto-optimality is demanded in this respect -- for the most part by economists. A social condition is pareto-optimal or pareto-efficient when it is not possible to shift to another condition judged better by at least one person and worse by none (Sen 1970, chap. 2, 2*). A widely discussed alternative to the Pareto principle is the Kaldor-Hicks welfare criterion. This stipulates that a rise in social welfare is always present when the benefits accruing through the distribution of value in a society exceed the corresponding costs. A change thus becomes desirable when the winners in such a change could compensate the losers for their losses and still retain a substantial profit. In contrast to the Pareto-criterion, the Kaldor-Hicks criterion contains a compensation rule (Kaldor 1939). For purposes of economic analysis, such theoretical models of optimal efficiency make a great deal of sense. However, the analysis is always made relative to starting situation that can be unjust and unequal. A society can thus be (close to) pareto-optimality -- i.e., no one can increase his or her material goods or freedoms without diminishing those of someone else -- while also displaying enormous inequalities in the distribution of the same goods and freedoms. For this reason, egalitarians claim that it may be necessary to reduce pareto-optimality for the sake of justice if there is no more egalitarian distribution that is also pareto-optimal. In the eyes of their critics, equality of whatever kind should not lead to some people having to do with less even though this equalizing down does not benefit any of those who are in a worse position.

(iv) *Moral objections*: A strict and mechanical equal distribution between all individuals does not sufficiently take into account the differences among individuals and their situations. In essence, since individuals desire different things, why should everyone receive the same? Intuitively, for example, we can recognize that a sick person has other claims than a healthy person, and furnishing each with the same things would be mistaken. With simple equality, personal freedoms are unacceptably limited and distinctive individual qualities insufficiently regarded; in this manner they are in fact unequally regarded. Furthermore, persons not only have a moral right to their own needs being considered, but a right and a duty to take responsibility for their own decisions and their consequences.

Working against the identification of distributive justice with simple equality, a basic postulate of virtually all present-day egalitarians is as follows: human beings are themselves responsible for certain inequalities resulting from their free decisions; aside from minimum aid in emergencies, they deserve no recompense for such inequalities. On the other hand, they are due compensation for inequalities that are not the result of self-chosen options. For egalitarians, the world is morally better when *equality of life conditions* prevail. This is an amorphous ideal demanding further clarification. Why is such equality an ideal, and equality of what, precisely?

By the same token, most egalitarians presently do not advocate an equality of outcome, but different kinds of equality of opportunity, due to their emphasis on a pair of morally central points: firstly, that individuals have responsibility for their decisions; and secondly, that the only things to be considered objects of equality are things serving the real interests of individuals. The opportunities to be equalized between people can be opportunities for well-being (i.e. objective welfare), or for preference satisfaction (i.e., subjective welfare), or for resources. It is not equality of objective or subjective well-being or resources themselves that should be equalized, but an equal opportunity to gain the well-being or resources one aspires to. Such equality of opportunity (to well-being or resources) depends on the presence of a realm of options for each individual equal to the options enjoyed by all other persons, in the sense of the same prospects for fulfillment of preferences or the possession of resources. The opportunity must consist of possibilities one can really take advantage of. Equal opportunity prevails when human beings effectively enjoy equal realms of possibility.

(v) Simple equality is very often associated with equality of results (although these are two distinct concepts). However, to strive only for equality of results is problematic. To illustrate the point, let us briefly limit the discussion to a single action and the event or state of affairs resulting from it. Arguably, actions should not be judged solely by the moral quality of their results as important as this may be. One also has to take into consideration the way in which the events or circumstances to be evaluated have come about. Generally speaking, a moral judgement requires not only the assessment of the results of the action in question (the consequentialist aspect) but, first and foremost, the assessment of the

intention of the actor (the deontological aspect). The source and its moral quality influence the moral judgement of the results (Pogge 1999, sect. V). For example, if you strike me, your blow will hurt me; the pain I feel may be considered bad in itself, but the moral status of your blow will also depend on whether you were (morally) allowed such a gesture (perhaps through parental status, although that is controversial) or even obliged to execute it (e.g. as a police officer preventing me from doing harm to others), or whether it was in fact prohibited but not prevented. What is true of individual actions (or their omission) has to be true *mutatis mutandis* of social institutions and circumstances like distributions resulting from collective social actions (or their omission). Hence social institutions are to be assessed not solely on the basis of information about how they affect individual quality of life. A society in which people starve on the streets is certainly marked by inequality; nevertheless, its moral quality, i.e., whether the society is just or unjust with regard to this problem, also depends on the suffering's causes. Does the society allow starvation as an unintended but tolerable side effect of what its members see as a just distributive scheme? Indeed, does it even defend the suffering as a necessary means, e.g. as a sort of Social Darwinism? Or has the society taken measures against starvation which have turned out insufficient? In the latter case, whether the society has taken such steps for reasons of political morality or efficiency again makes a moral difference. Hence even for egalitarians, equality of results is too narrow and one-sided a focus.

(vi) Finally, there is a danger of (strict) equality leading to uniformity, rather than to a respect for pluralism and democracy (Cohen 1989; Arneson 1993). In the contemporary debate, this complaint has been mainly articulated in feminist and multiculturalist theory. A central tenet of feminist theory is that gender has been and remains a historical variable and internally differentiated relation of domination. The same holds for so called racial and ethnic differences. These differences are often still conceived of as marking different values. The different groups involved here rightly object to their discrimination, marginalization, and domination, and an appeal to equality of status thus seems a solution. However as feminists and multiculturalists have pointed out, equality, as usually understood and practiced, is constituted in part by a denial and ranking of differences; as a result it seems less useful as an antidote to relations of domination. "Equality" can often mean the assimilation to a pre-existing and problematic ‘male’ or ‘white’ or ‘middle class’ norm. In short, domination and a fortiori inequality often arises out of an inability to appreciate and nurture differences -- not out of a failure to see everyone as the same. To recognize these differences should however not lead to an essentialism grounded in sexual or cultural characteristics. In contemporary multiculturalism and feminism, there is a crucial debate between those who insist that sexual, racial, and ethnic differences should become irrelevant, on the one hand, and those believing that such differences, even though culturally relevant, should not furnish a basis for inequality: that rather one should find mechanisms for securing equality, despite valued differences. Neither of these strategies involves rejecting equality. Rather, the dispute is about how equality is to be attained (McKinnon 1989, Taylor 1992).

> Proposing a connection between equality and pluralism, Michael Walzer's theory (1983) aims at what he calls "complex equality". According to Walzer, relevant reasons can only speak in favor of distribution of specific types of goods in specific spheres -- not in several or all spheres. Against a theory of simple equality promoting equal distribution of dominant goods, hence underestimating the complexity of the criteria at work in each given sphere the dominance of particular goods needs to be ended. For instance, purchasing power in the political sphere through means derived from the economic sphere (i.e., money) needs to be prevented. Actually, Walzer's theory of complex equality is not aimed at equality but at the separation of spheres of justice, the theory's designation thus being misleading. Any theory of equality should however follow Walzer's advice not to be monistic but recognize the complexity of life and the plurality of criteria for justice.

We thus arrive at the following desideratum: instead of *simple* equality, we need a concept of more *complex* equality: a concept managing to resolve the above problems through a distinction of various classes of goods, a separation of spheres, and a differentiation of relevant criteria.

3.2 Libertarianism

Libertarianism and *economic liberalism* represent minimalist positions in relation to distributive justice. Citing Locke, they both postulate an original right to freedom and property, thus arguing against redistribution and social rights and for the free market (Nozick 1974; Hayek 1960). They assert an opposition between equality and freedom: the individual (natural) right to freedom can be limited only for the sake of foreign and domestic peace. For this reason, libertarians consider maintaining public order the state's only legitimate duty. They assert a natural right to self-ownership (the philosophical term for "ownership of oneself" -- i.e., one's will, body, work, etc.) that entitles everybody to thus far unowned bits of the external world by means of mixing their labor with it. All individuals can thus claim property if "enough and as good" is left over for others (Locke's proviso). Correspondingly, they defend market freedoms and oppose the use of redistributive taxation schemes for the sake of social justice as equality. A principal objection to libertarian theory is that its interpretation of the Lockean proviso -- nobody's situation should be worsened through an initial acquisition of property -- leads to an excessively weak requirement and is thus unacceptable (Kymlicka 1990, pp.108-117). With a broader and more adequate interpretation of what it means for one a situation to be worse than another, however, justifying private appropriation and, *a fortiori*, all further ownership rights, becomes much more difficult. If the proviso recognizes the full range of interests and alternatives that self-owners have, then it will not generate unrestricted rights over unequal amounts of resources. Another objection is that precisely if one's own free accomplishment is what is meant to count, as the libertarians argue, success should not depend strictly on luck, extraordinary natural gifts, inherited property, and status. In other words, *equal opportunity* also needs to at least be present as a counterbalance, ensuring that the fate of human beings is determined by their decisions and not by unavoidable social circumstances. Equal opportunity thus seems to be the frequently vague minimal formula at work in every egalitarian conception of distributive justice. Many egalitarians, however, wish for more -- namely, an *equality of (at least basic) life conditions*.

In any event, with a shift away from a strictly negative idea of freedom, economic liberalism can indeed

itself point the way to more social and economic equality. For with such a shift, what is at stake is not only assuring an equal right to self-defense, but also furnishing everyone more or less the same chance to actually make use of the right to freedom (e.g. Van Parijs 1995, Steiner 1994). In other words, certain basic goods need to be furnished to assure the equitable or 'fair value of the basic liberties' (Rawls 1993, pp. 356-63).

3.3 Utilitarianism

It is possible to interpret utilitarianism as concretizing moral equality -- and this in a way meant to offer the same consideration to the interests of all human beings (Kymlicka 1990, pp. 31f., Hare 1981, p. 26, Sen 1992, pp. 13f.). From the utilitarian perspective, since everyone counts as one and no one as more than one (Bentham), the interests of all should be treated equally without consideration of contents of interest or an individual's material situation. For utilitarianism this means that all enlightened personal interests have to be fairly aggregated. The morally proper action is the one that maximizes utility (Hare 1984). But this utilitarian conception of equal treatment has been criticized as inadequate by many opponents of utilitarianism. At least in utilitarianism's classical form -- so the critique reads -- the hoped for moral equality is flawed: this because all desires are taken up by the utilitarian calculation -- including "selfish" and "external" preferences (Dworkin 1977, p. 234), all having equal weight, even when they diminish the 'rights' and intentions of others. And this, of course, conflicts with our everyday understanding of equal treatment. What is here at play is an argument involving "offensive" and "expensive" taste: a person cannot expect others to sustain his or her desires at the expense of their own (Kymlicka 1990, p. 40 f.). Rather, according to generally shared conviction, equal treatment consistently requires a basis of equal rights and resources that cannot be taken away from one person, whatever the desire of others. In line with Rawls (1971, pp. 31, 564, cf. 450), many hold that justice entails according no value to interests insofar as they conflict with justice. According to this view, unjustified preferences will not distort mutual claims people have on each other. Equal treatment has to consist of everyone being able to claim a fair portion, and not in all interests having the same weight in disposal over my portion. Utilitarians cannot admit any restrictions on interests based on morals or justice. As long as utilitarian theory lacks a concept of justice and fair allotment, it must fail in its goal of treating all as equals. As Rawls (1971, pp. 27) also famously argues, utilitarianism that involves neglecting the separateness of persons does not contain a proper interpretation of moral equality as equal respect for each individual.

3.4 Equality of Welfare

The concept of welfare equality is motivated by an intuition that when it comes to political ethics, what is at stake is the individual's well-being. The central criterion for justice must consequently be equalizing the level of welfare. But taking welfare as what is to be equalized leads into major difficulties, which resemble those of utilitarianism. If one contentiously identifies subjective welfare with preference satisfaction, it seems implausible to count all individual preferences as equal, some -- such as the desire to do others wrong -- being inadmissible on grounds of justice (the offensive taste argument). Any welfare-centered concept of equality grants people with refined and expensive taste more resources -- something

distinctly at odds with our moral intuitions (the expensive taste argument) (Dworkin 1981a). However, satisfaction in the fulfillment of desires cannot serve as a standard, since we wish for more than a simple feeling of happiness. A more viable standard for welfare comparisons would seem to be success in the fulfillment of preferences. A fair evaluation of such success cannot be purely subjective, rather requiring a standard of what should or could have been achieved. And this itself involves an assumption regarding just distribution; it is thus no independent criterion for justice. An additional serious problem with any welfare-centered concept of equality is that it cannot take account of either desert (Feinberg 1970) or personal responsibility for one's own well-being, to the extent this is possible and reasonable.

3.5 Equality of Resources

Represented above all by both Rawls and Dworkin, resource equality avoids such problems (Rawls 1971; Dworkin 1981b). It holds individuals responsible for their decisions and actions, not, however, for circumstances beyond their control -- race, sex, and skin-color, but also intelligence and social position -- which thus are excluded as distributive criteria. Equal opportunity is insufficient because it does not compensate for unequal innate gifts. What applies for social circumstances should also apply for such gifts, both these factors being purely arbitrary from a moral point of view and requiring adjustment.

According to Rawls, human beings should have the same initial expectations of "basic goods," i.e., all-purpose goods; this in no way precludes ending up with different quantities of such goods or resources, as a result of personal economic decisions and actions. When prime importance is accorded an assurance of equal basic freedoms and rights, inequalities are just when they fulfill two provisos: on the one hand, they have to be linked to offices and positions open to everyone under conditions of fair equality of opportunity; on the other hand, they have to reflect the famous ‘difference principle’ in offering the greatest possible advantage to the least advantaged members of society (Rawls 1993, p. 5 f.; 1971, § 13). Otherwise, the economic order requires revision. Due to the argument of the moral arbitrariness of talents, the commonly accepted criteria for merit (like productivity, working hours, effort) are clearly relativized. The difference principle only allows the talented to earn more to the extent this raises the lowest incomes. According to Rawls, with regard to the basic structure of society, the difference principle should be opted for under a self-chosen "veil of ignorance" regarding personal and historical circumstances and similar factors: the principle offers a general assurance of not totally succumbing to the hazards of a free market situation; and everyone does better than with inevitably inefficient total equal distribution, whose level of well-being is below that of those worst off under the difference principle.

Since Rawls' *Theory of Justice* is the classical focal point of present-day political philosophy, it is worth noting the different ways his theory claims to be egalitarian: First, Rawls upholds a natural basis for equal human worth: a minimal capacity for having a conception of the good and a sense of justice. Second, through the device of the "veil of ignorance," people are conceived as equals in the "original position." Third, the idea of sharing this "original position" presupposes the parties having political equality, as equal participants in the process of choosing the principles by which they would be governed. Fourth, Rawls proposes fair equality of opportunity. Fifth, Rawls maintains that all desert must be institutionally defined, depending on the goals of the society. No one deserves his or her talents or circumstances -- all products of the natural lottery. Finally, the difference principle tends toward equalizing holdings.

Dworkin's equality of resources (1981b) stakes a claim to being even more ‘ambition-sensitive’ and endowment-insensitive’ than Rawls' theory. Unequal distribution of resources is considered fair only when it results from the decisions and intentional actions of those concerned. Dworkin proposes a hypothetical auction in which everyone can accumulate bundles of resources through equal means of payment, so that in the end no one is jealous of another's bundle (the envy test). The auction-procedure also offers a way to precisely measure equality of resources: the measure of resources devoted to a person's life is defined by the importance of the resources to others (Dworkin 1981b, p. 290). In the free market, how the distribution then develops depends on an individual's ambitions. The inequalities that thus emerge are justified, since one has to take responsibility for one's "option luck" in the realm of personal responsibility. In contrast, unjustified inequalities based on different innate provisions and gifts as well as brute luck should be compensated for through a fictive differentiated insurance system: its premiums are established behind Dworkin's own ‘veil of ignorance,’ in order to then be distributed in real life to everyone and collected in taxes. For Dworkin, this is the key to the natural lottery being balanced fairly, preventing an "slavery of the talented" through excessive redistribution.

Objections to all versions of "brute-luck egalitarianism" come from two sides. Some authors criticize its in their view unjustified or excessively radical rejection of merit: The egalitarian thesis of desert only being justifiably acknowledged if it involves desert "all the way down" (Nozick 1974, p. 225) not only destroys the classical, everyday principle of desert, since everything has a basis that we ourselves have not created. In the eyes of such critics, along with the merit-principle this argument also destroys our personal identity, since we can no longer accredit ourselves with our own capacities and accomplishments. (Cf. the texts in Pojman & McLeod 1998.) Other authors consider the criterion for responsibility to be too strong, indeed inhuman in its consequences, since human beings responsible for their own misery would be left alone with their misery (Anderson 1999).

3.6 Equality of Opportunity for Welfare or Advantage

Approaches based on equality of opportunity can be read as revisions of both welfarism and resourcism. Ranged against welfarism and designed to avoid its pitfalls, they incorporate the powerful ideas of choice and responsibility into various, improved forms of egalitarianism. Such approaches are meant to equalize outcomes, insofar as they are the consequences of causes beyond a person's control (i.e., beyond circumstances or endowment), but to allow differential outcomes in so far as they result from autonomous choice or ambition. But the approaches are also aimed at maintaining the insight that individual preferences have to count, as the sole basis for a necessary linkage back to the individual perspective: otherwise, there is an overlooking of the person's value. In Arneson's (1989, 1990) concept of *equal opportunity for welfare*, the preferences determining the measure of individual well-being are meant to be conceived hypothetically -- i.e., a person would decide on them after a process of ideal reflection. In order to correspond to the morally central vantage of personal responsibility, what should be equalized are not enlightened preferences themselves, but rather real opportunities to achieve or receive a good, to the extent that it is aspired to. G.A. Cohen's (1989, p. 916 f.) broader conception of *equality of access to advantage* attempts to link and integrate the perspectives of welfare equality and resource equality

through the overriding concept of advantage. For Cohen, there are two grounds for egalitarian compensation. Egalitarians will be moved to furnish a paralyzed person with a compensatory wheelchair independently of the person's welfare level. This egalitarian response to disability overrides equality of (opportunity to) welfare. Egalitarians also favor compensation for phenomena such as pain, independent of any loss of capacity -- for instance by paying for expensive medicine. But, Cohen claims, any justification for such compensation has to invoke the idea of equality of opportunity to welfare. He thus views both aspects, resources and welfare, as necessary and irreducible. Much of Roemer's (1998) more technical argument is devoted to constructing the scale to calibrate the extent to which something is the result of circumstances. An incurred adverse consequence is the result of circumstances, not choice, precisely to the extent that it is a consequence that persons of one or another specific type can be expected to incur.

3.7 Capabilities Approaches

Theories that limit themselves to the equal distribution of basic means -- this in the hope of doing justice to the different goals of all human beings -- are often criticized as fetishistic, in that they focus on means, rather than on what individuals gain with these means (Sen 1980). For the value goods have for someone depends on objective possibilities, the natural environment, and individual capacities. Hence in contrast to the resourcist approach, Amartya Sen proposes orientating distribution around "capabilities to achieve functionings," i.e., the various things that a person manages to do or be in leading a life (Sen 1992). In other words, evaluating individual well-being has to be tied to a capability for achieving and maintaining various precious conditions and "functionings" constitutive of a person's being, such as adequate nourishment, good health, the ability to move about freely or to appear in public without shame, and so forth. Also important here is the real freedom to acquire well-being -- a freedom represented in the capability to oneself choose forms of achievement and the combination of "functionings." For Sen, capabilities are thus the measure of an *equality of capabilities* human beings enjoy to lead their lives. A problem consistently raised with capability approaches is the ability to weigh capabilities in order to arrive at a metric for equality. The problem is intensified by the fact that various moral perspectives are comprised in the concept of capability (Cohen 1993, p. 17-26, Williams 1987). Martha Nussbaum (1992, 2000) has linked the capability approach to an Aristotelian, essentialistic, "thick" theory of the good -- a theory meant to be, as she puts it, "vague," incomplete, and open-ended enough to leave place for individuality and cultural variations. On the basis of such a "thick" conception of necessary and universal elements of a good life, certain capabilities and functionings can be designated as foundational. In this manner, Nussbaum can endow the capability approach with a precision that furnishes an index of interpersonal comparison, but at some risk: that of not being neutral enough regarding the plurality of personal conceptions of the good ? a neutrality normally required by most liberals (most importantly Rawls 1993).

4. Equality Among Whom?

Justice is primarily related to individual actions. Individual persons are the primary bearers of responsibility (the key principle of ethical individualism). This raises two controversial issues in the

contemporary debate.

One could regard the norms of distributive equality as applying to groups rather than individuals. It is often groups that rightfully raise the issue of an inequality between themselves and the rest of society -- e.g. women; so-called racial and ethnic groups. The question arises of whether inequality among such groups should be considered morally objectionable in itself, or whether even in the case of groups, the underlying concern should be how individuals (as members of such groups) fare in comparative terms.

Do the norms of distributive equality (whatever they are) apply to all individuals, regardless of where (and when) they live? Or rather, do they only hold for members of communities within states and nations? Most theories of equality deal exclusively with distributive equality among people in a single society. But there does not seem to be any rationale for that limitation. Can the group of the entitled be restricted prior to the examination of concrete claims? Many theories seem to imply this when they connect distributive justice or the goods to be distributed with social cooperation or production. For those who contribute nothing to cooperation, such as the disabled, children, or future generations, would have to be denied a claim to a fair share. The circle of persons who are to be the recipients of distribution would thus be restricted from the outset. Other theories are less restrictive, insofar as they do not link distribution to actual social collaboration, yet nonetheless do restrict it, insofar as they bind it to the status of citizenship. In this view, distributive justice is limited to the individuals within a society. Those outside the community have no entitlement to social justice. Unequal distribution among states and the social situations of people outside the particular society could not, in this view, be a problem of social distributive justice. Yet here too, the universal morality of equal respect and the principle of equal distribution demand that we consider each person as prima facie equally entitled to the goods, unless reasons for an unequal distribution can be put forth. It may be that in the process of justification, reasons will emerge for privileging those who were particularly involved in the production of a good. But prima facie, there is no reason to exclude from the outset other persons, e.g. those from other countries, from the process of distribution and justification. That may seem most intuitively plausible in the case of natural resources (e.g. oil) that someone discovers by chance on or beneath the surface of his or her property. Why should such resources belong to the person who discovers them, or on whose property they are located? Nevertheless, in the eyes of many if not most people, global justice, i.e., extending distributive justice globally, demands too much from individuals and their states (Miller 1998). The charge, open, of course, to challenge, is one of excessive demands being made.

5. The Value of Equality: Why Equality?

Does equality play a major role in a theory of justice, and if so, what is this role?

A conception of justice is *egalitarian* when it views equality as a fundamental goal of justice. L. Temkin has put it as follows: "an egalitarian is any person who attaches *some* value to equality *itself* (that is, any person that cares *at all* about equality, over and above the extent it promotes other ideals). So, equality needn't be the only value, or even the ideal she values most....Egalitarians have the deep and (for them) compelling view that it is a bad thing -- unjust and unfair -- for some to be worse off than others through

no fault of their own." (Temkin 1986, p. 100, cf. 1993, p. 7). In general, the focus of the modern egalitarian effort to realize equality is on the possibility of a good life, i.e., on an equality of life prospects and life circumstances -- interpreted in various ways according to various positions in the "equality of what" debate (see above).

I maintain the presence of three sorts of egalitarianism: intrinsic, instrumental and constitutive. (For a two fold distinction cf. Parfit 1997, Temkin 1993, p. 11, McKerlie, 1996, p. 275.) Intrinsic egalitarians view equality as an intrinsic good in itself. As pure egalitarians, they are concerned solely with equality, most of them with equality of social circumstances, according to which it is intrinsically bad if some people are worse off than others through no fault of their own. But it is in fact the case that we do not always consider inequality a moral evil. Intrinsic egalitarians regard equality as desirable even when the equalization would be of no use to any of the affected parties -- e.g. when equality can only be produced through depressing the level of everyone's life. But something can only have an intrinsic value when it is good for at least one person, i.e., makes one life better in some way or another. The following "leveling-down" objection indicates that doing away with inequality in fact ought to produce better circumstances -- it otherwise being unclear why equality should be desired. (For such an objection, cf. Nozick 1974, p. 229, Raz 1986, chap. 9, p. 227, 235, Temkin 1993, pp. 247-8.) Sometimes inequality can only be ended by depriving those who are better off of their resources, rendering them as poorly off as everyone else. (For anyone looking for a drastic literary example, Kurt Vonnegut's science-fiction story *Harrison Bergeron* (1950) is recommended.) This would have to be an acceptable approach according to the intrinsic concept. But would it be morally good if, in a group consisting of both blind and seeing persons, those with sight were rendered blind because the blind could not be offered sight? That would in fact be morally perverse. Doing away with inequality by bringing everyone down contains -- so the objection -- nothing good. Such leveling-down objections would of course only be valid if there were indeed no better and equally egalitarian alternatives available; and nearly always there are such: e.g. those who can see should have to help the blind, financially or otherwise. In case there are no alternatives, in order to avoid such objections, intrinsic egalitarianism cannot be strict, but needs to be *pluralistic*. Then intrinsic egalitarians could say there is something good about the change, namely greater equality -- although they would concede that much is bad about it. Pluralistic egalitarians do not have equality as their only goal; they also admit other values and principles -- above all the principle of welfare, according to which it is better when people are doing better. In addition, pluralistic egalitarianism should be *moderate* enough to not always grant equality victory in the case of conflict between equality and welfare. Instead, it needs to be able to accept reductions in equality for the sake of a higher quality of life for all (as e.g. with Rawls' difference principle).

At present, many egalitarians are ready to concede that equality in the sense of equality of life circumstances has no compelling value in itself; but that, in a framework of liberal concepts of justice, its meaning emerges in pursuit of other ideals: universal freedom, full development of human capacities and the human personality, the mitigation of suffering and defeat of domination and stigmatization, the stable coherence of modern, freely constituted societies, and so forth (Scanlon 1996). For those who are worse off, unequal circumstances often mean considerable (relative) disadvantages and many (absolute) evils; and as a rule these (relative) disadvantages and (absolute) evils are the source for our moral condemnation of unequal circumstances. But this does not mean that inequality as such is an evil. Hence,

the argument goes, fundamental moral ideals other than equality stand behind our aspiring for equality. When we are against inequality on such grounds, we are for equality either as a byproduct or as a means and not as a goal or intrinsic value. In its treatment of equality as a derived virtue, the sort of egalitarianism -- if the term is actually suitable -- here at play is *instrumental*.

As indicated, there is also a third, more suitable approach to the equality ideal: a *constitutive* egalitarianism. According to this approach, we aspire to equality on other moral grounds -- namely, because certain inequalities are unjust. Equality has value, but this is an extrinsic value, since it derives from another, higher moral principle of equal dignity and respect. But it is not instrumental for this reason, i.e., it is not only valued on account of moral equality, but also on its own account. (For the distinction between the origin of a value and the kind of value it is, cf. Korsgaard 1996.) Equality stands in relation to justice as does a part to a whole. The requirement of justification is based on moral equality; and in certain contexts, successful justification leads to the above-named principles of equality, i.e., formal, proportional equality and the presumption of equality. Thus according to constitutive egalitarianism, these principles and the resulting equality are justified and required by justice, and by the same token constitute social justice.

We should further distinguish two levels of egalitarianism and non-egalitarianism, respectively. On a first level, a constitutive egalitarian presumes that every explication of the moral standpoint is incomplete without terms such as ‘equal,’ ‘similarly,’ etc. In contrast, a non-egalitarianism operating on the same level considers such terms misplaced or redundant. On a second level, when it comes to concretizing and specifying conceptions of justice, a constitutive egalitarian gives equality substantive weight. On this level, we can find more and less egalitarian positions according to the chosen currency of equality (the criteria by which just equality is measured) and according to the reasons for unequal distributions (exemptions of the presumption of equality) the respective theories regard as well grounded. Egalitarianism on the second level thus relates to the kind, quality and quantity of things to be equalized. Because of such variables, a clear-cut definition of second level egalitarianism cannot be formulated. In contrast, non-egalitarians on this second level advocate a non-relational entitlement theory of justice.

Alongside the often-raised objections against equality mentioned in the section on "simple equality" there is a different and more fundamental critique formulated by first level non-egalitarians: that equality does not have a foundational role in the grounding of claims to justice. While the older version of a critique of egalitarianism comes mainly from a the right side of the political spectrum, thus arguing in general against "patterned principles of justice" (Nozick 1974, esp. pp. 156-157), the critique's newer version also often can be heard in liberal circles (Walzer 1983, Raz 1986, chap. 9, Frankfurt 1987. 1997, Parfit 1997, Anderson 1999). This first-level critique of equality poses the basic question of why justice should in fact be conceived relationally and (what is here the same) comparatively. Referring back to Joel Feinberg's (1974) distinction between comparative and non-comparative justice, non-egalitarians object to the moral requirement to treat people as equals and many demands for justice emerging from it. They argue that neither the postulate nor these demands involve comparative principles -- let alone any equality principles. They reproach first-level egalitarians for a confusion between "equality" and "universals." As the non-egalitarians see things, within many principles of justice -- at least the especially important ones -- the equality-terminology is redundant. Equality is thus merely a byproduct of the general fulfillment of

actually non-comparative standards of justice: something obscured through the unnecessary inserting of an expression of equality (Raz 1986, p. 227f.). At least the central standards of dignified human life are not relational but "absolute." As Harry Frankfurt puts it: "It is whether people have good lives, and not how their lives compare with the lives of others." (Frankfurt 1997, p. 6) And again: "The fundamental error of egalitarianism lies in supposing that it is morally important whether one person has less than another regardless of how much either of them has." (Frankfurt 1987, p. 34)

From the non-egalitarian vantage, what is really at stake in helping those worse off and improving their lot is *humanitarian concern*, a desire to alleviate suffering. Such concern is understood as not egalitarian. It is not centered on the difference between those better off and those worse off as such (whatever the applied standard), but on improving the situation of persons in bad circumstances. Their distress constitutes the actual moral foundation. The wealth of those better off only furnishes a means that has to be transferred for the sake of mitigating the distress, as long as other, morally negative consequences do not emerge in the process. The strength of the impetus for more equality lies in the urgency of the claims of those worse off, not in the extent of the inequality. For this reason, instead of equality the non-egalitarian critics favor one or another *entitlement theory of justice*, such as Nozick's (1974) libertarianism (cf. 3.2. above) and Frankfurt's (1987) *doctrine of sufficiency*, according to which "What is important from the moral point of view is not that everyone should have *the same* but that each should have *enough*. If everyone had enough, it would be of no moral consequence whether some had more than others." (Frankfurt 1987, p. 21) Parfit's (1997) *priority view* accordingly calls for focus on improving the situation of society's weaker and poorer members and indeed all the more urgently the worse off they are, even if they can be less helped than others in the process. In any case, entitlement-based non-egalitarian arguments can result in praxis in an equality of outcome as far-reaching as egalitarian theories. Hence fulfilling an absolute or non-comparative standard for everyone (e.g. to the effect that nobody should starve) frequently results in a certain equality of outcome, such a standard comprising not only a decent living but a good life. Consequently, the debate here centers on the basis -- is it equality or something else? -- and not so much on the outcome -- are persons or groups more or less equal, according to a chosen metric? Possibly, the difference is even deeper, lying in the conception of morality in general, rather than in equality at all.

Egalitarians can respond to the anti-egalitarian critique by conceding that it is the nature of some (if certainly far from all) essential norms of morality and justice to be concerned primarily with the adequate fulfillment of the separate claims of individuals. However whether a claim can itself be considered suitable can be ascertained only by asking whether it can be agreed on by all those affected in hypothetical conditions of freedom and equality. This justificatory procedure is all the more needed the less evident -- indeed the more unclear or controversial -- it is if what is at stake is actually suffering, distress, an objective need. In the view of the constitutive egalitarians, all the judgments of distributive justice should be approached relationally by asking which distributive scheme all concerned parties can universally and reciprocally agree to. As described at some length in the pertinent section above, many egalitarians argue that a presumption in favor of equality follows from this justification requirement. In the eyes of such egalitarians, this is all one needs for the justification and determination of the constitutive value of equality.

Secondly, even if -- for the sake of argument -- the question is left open of whether demands for distribution according to objective needs (e.g. alleviating hunger) involve non-comparative entitlement-claims, it is nonetheless always necessary to resolve the question of what we do owe needy individuals. And this is tied in a basic way to the question of what we owe persons in comparable or worse situations, and how we need to invest our scarce resources (money, goods, time, energy) in light of the sum total of our obligations. While the claim on our help may well appear non-relational, determining the kind and extent of the help must always be relational -- at least in circumstances of scarcity (and resources are always scarce). Claims are either "satiable" (Raz 1986, p. 235), i.e., an upper limit or sufficiency level can be indicated after which each person's claim to X has been fulfilled, or they are not so. For insatiable claims, to stipulate any level at which one is or ought to be sufficiently satisfied is arbitrary. If the standards of sufficiency are defined as a bare minimum, why should persons be content with that minimum? Why should the manner in which welfare and resources are distributed above the poverty level not also be a question of justice? If, by contrast, we are concerned solely with claims that are in principle "satiable," such claims having a reasonable definitions of sufficiency, then these standards of sufficiency will most likely be very high. In Frankfurt's definition, for example, sufficiency is reached only when persons are satisfied and no longer actively strive for more. Since we find ourselves operating, in practice, in circumstances far beneath such a high sufficiency level, we (of course) live in (moderate) scarcity. Then the above mentioned argument holds as well -- namely, that in order to determine to what extent it is to be fulfilled, each claim has to be judged in relation to the claims of all others and all available resources. In addition, the moral urgency of lifting people above dire poverty cannot be invoked to demonstrate the moral urgency of everyone having enough. In both forms of scarcity, i.e., with satiable and insatiable claims, the social right or claim to goods cannot be conceived as something absolute or non-comparative. Egalitarians may thus conclude that distributive justice is always comparative. This would suggest that distributive equality, especially equality of life-conditions, is due a fundamental role in an adequate theory of justice in particular and of morality in general.

William Godwin

William Godwin (1756-1836) was the founder of philosophical anarchism. In his *An Enquiry Concerning Political Justice* (1793) he argued that government is a corrupting force in society, perpetuating dependence and ignorance, but that it will be rendered increasingly unnecessary and powerless by the gradual spread of knowledge. Politics will be displaced by an enlarged personal morality as truth conquers error and mind subordinates matter. In this development the rigorous exercise of private judgment, and its candid expression in public discussion, plays a central role, motivating his rejection of a wide range of co- operative and rule-governed practices which he regards as tending to mental enslavement, such as law, private property, marriage and concerts. Epitomising the optimism of events in France at the time he began writing, Godwin looked forward to a period in which the dominance of mind over matter would be so complete that mental perfectibility would take a physical form, allowing us to control illness and ageing and become immortal.

Godwin's moral theory is often described as utilitarian. He clearly does play an important part in the history of utilitarianism, not least for his invocation of both British and French writers in the tradition, such as Joseph Priestley and d'Holbach and Helvetius, and for the way that his ethical theory is underpinned by a distinctive rationalist necessarianism on the basis of which he insisted on a strong form of first order impartiality. One of Godwin's lasting contributions to moral philosophy, ‘the famous fire cause’, in which we are asked to consider whom I should save from a burning room if I can only save one person and if the choice is between Archbishop Fénelon and a common chambermaid. Fénelon is about to compose his immortal *Télémaque* and the chambermaid turns out to be my mother. Godwin's conclusion that we must save the former relies on consequentialist grounds. However, since his account of the content of utility is inseparable from the development of truth and wisdom, and since we can best promote this through the full and free exercise of private judgment and public discussion, the resulting position looks more like a form of perfectionism than utilitarianism.

Godwin's philosophical importance rests principally on his *Political Justice*. He wrote other philosophical works, *The Enquirer* (1798) and *Thoughts on Man* (1831), but he has become perhaps better known for his novels, the most famous of which is *Caleb Williams* (1794), and for the part he played in literary London from 1783-1836 - from his heyday in the 1790s as the radical philosopher who married Mary Wollstonecraft, through the next forty years in which he was variously the butt of attacks by Thomas Malthus, Samuel Parr and a host of anti-jacobin scribes, friend of the romantic poets, publisher and author of children's books, father-in-law and sponger off Percy Bysshe Shelley, and historian of the Civil War, to his final anomalous position as a government pensioner supported by a Tory administration. His papers and his diary, which sparsely records what he read and wrote and whom he met, provide an

immense resource for scholars of the romantic period.

Life

Godwin was born on 3 March 1756 at Wisbeach, Cambridgeshire, the seventh of thirteen children of John Godwin (1723-1772) a dissenting minister, and his wife Anne (c1723-1809), the daughter of Richard Hull, a ship-owner engaged in the Baltic trade. As a minister Godwin's father was involved in a number of conflicts with his congregations and the family moved first from Wisbeach to Debenham, Suffolk and, in 1760 to Guestwick, near Norwich, Norfolk, where they lived until his father's death. The village was small and the revenue poor; to supplement their income they took in pupils to whom John Godwin taught the classics. The family's financial circumstances improved on the death of Edward Godwin (1695-1764), Godwin's paternal grandfather -- also a dissenting minister and friend of Philip Doddridge, in whose Academy Godwin's father and his uncle Edward had been educated. Godwin's upbringing was rather gloomy. He was not a robust child and his aunt "instructed me to compose myself in sleep, with a temper as if I were never again to wake in this sublunary world." (‘Autobiography’ in *Collected Novels and Memoirs* (*CNM*), 1992, I, 12). At five he was reading *The Pilgrim's Progress* with her, together with James Janeway's *Account of the Conversion, holy and exemplary lives and joyful deaths of several young children* (1671-2), and hymns, catechisms and prayers written by Dr. Isaac Watts. One of Godwin's earliest memories was of composing a poem entitled ‘I wish to be a minister’ (*CNM* I, 15), and a favourite childhood entertainment was to preach sermons in the kitchen on Sunday afternoons.

He was first educated by a Mrs. Gedge, an elderly woman, ‘much occupied in the concerns of religion’, with whom he read the Old and New Testaments. After her death in 1764, he and his brother went to Mr. Akers' school in Hilderston (now Hindolverston). Godwin remained a religious enthusiast and dissenter -- preaching to his fellow schoolchildren, identifying some as ‘children of the devil’, and refusing to answer questions on the Collect of the week, taken from the *Book of Common Prayer* (*CNM* I, 24). His success at Akers' reinforced his commitment to intellectual activity and his aversion to physical toil, and compounded his pride, for which he was frequently admonished by his father. Despite his father's opposition, his resolution to become a minister never wavered, and in 1767 he went to board with a Mr. Samuel Newton, the minister of an independent congregation in Norwich.

Newton was deeply influenced by the writings of Robert Sandeman (1718-1771), a hyper-Calvinist who, scorned faith and presents God as saving or damning a person solely "according to the right or wrong judgment of the understanding" (*CNM* I, 30). Godwin compared Newton in his Autobiography to Caligula or Nero for his spiteful and violent treatment, and he left him in the early summer of 1770, having abandoned his calling and decided to become a bookseller. Six months at Hindolverston persuaded him to resume his pupillage for a further, final year, after which he was pronounced fit for entry into the Dissenting College at Homerton and discharged. Homerton turned him down "on suspicion of Sandemanianism" (*CNM* I, 41). The more tolerant Hoxton Academy, principally run by Andrew Kippis and Abraham Rees admitted him. Hoxton was noted for its Arminianism and Arianism (that is, for the belief that Divine sovereignty was compatible with free will in man and for the rejection of the divinity of Christ), but Godwin's Sandemanianism remained stubbornly untouched, although he supplemented it with "a creed upon materialism and immaterialism, liberty and necessity, in which no subsequent improvement of my understanding has been able to produce any variation." (*CNM* I, 42). In June 1778 he set out to practice his vocation. He had a brief appointment in Ware, followed by a period in London, apparently without income, before obtaining a post in 1780 at Stowmarket, Suffolk. He held the post for two years, during which time his religious beliefs underwent a revolution, moving towards deism after following the suggestion of one of his parishioners and reading Holbach, Helvetius and Rousseau. Not surprisingly, he fell into dispute with his congregation and moved to London in 1782 where friends encouraged him to write for his living.

Later that year he completed his first work, *The history of the Life of William Pitt, Earl of Chatham* (1783), and by the following year was contributing to the English Review, ‘at two guineas a sheet’. At the end of 1782 he returned briefly to his original profession, being employed at Beaconsfield in Buckinghamshire for seven months, during which he produced a volume of sermons, *Sketches of History* (1783). When this appointment broke down he returned to London and resumed his career as an author.

Godwin's output between 1782 and 1784 included, in addition to his *Life of Chatham* and his sermons, three novels, two political pamphlets, a work on education, and a spoof of the critical reviews. None made Godwin much money and it was only when his former tutor, Andrew Kippis, invited him to write the British and Foreign History section for the *New Annual Register*, in July 1784, that he was assured of an adequate income. He probably also made some money from the pieces he wrote in 1785 for the *Political Herald*, a Whig journal, edited by Dr. Gilbert Stuart. The pamphlets, and his pieces for the *Political Herald*, reveal him to be an extremely well informed commentator on contemporary affairs. Between 1785 and 1793 Godwin published little save his work for the *New Annual Register*. Nonetheless, in the summer of 1791, at the height of the debate on the French Revolution, sparked by Edmund Burke's *Reflections on the Revolution in France* (1790), he persuaded his publisher, George Robinson, to support him while he wrote a work summarising recent developments in political philosophy. The work grew from its original conception and was eventually published in two volumes in February 1793 as *An Enquiry Concerning Political Justice*. It is was an immediate success and remains the founding work of philosophical anarchism. Although Godwin drew on principles canvassed in the debate, and on the work of the *philosophes*, *Political Justice* was also powerfully influenced by Godwin's Dissenting education and his involvement in Dissenting circles around Kippis and Timothy and Thomas Brand Hollis. His

success soon made him a central figure in radical political and literary circles of London; he become friends with John Thelwall, Holcroft, and John Horne Tooke (all of whom were indicted for Treason in 1794), he associated with a wide range of other established writers such as Elizabeth Inchbald, James Mackintosh, and Joseph Ritson, and he was sought out by a younger generation of enthusiasts, including William Wordsworth, Samuel Taylor Coleridge and William Hazlitt. In May 1794 Godwin's most successful novel, *Things as they are, or The adventures of Caleb Williams* was published, adding further to his literary reputation, and in the October of that year his shrewd political pamphlet, *Cursory Strictures on the Charge delivered by Lord Chief Justice Eyre to the Grand Jury*, attacked the case for Treason constructed by Eyre against the leaders of the London Corresponding Society and the Society for Constitutional Information, several of whom were his close associates.

A second edition of Godwin's *Political Justice*, in which some of the more rationalist and utopian statements of the first edition were modified, was published at the end of 1795. Shortly thereafter he became reacquainted with Mary Wollstonecraft, whom he had first met briefly in 1791 at a dinner in honour of Paine at which neither was much impressed by the other. Wollstonecraft had subsequently lived in revolutionary France and had had a child in a fraught relationship with Captain Gilbert Imlay, an American merchant. Their second introduction was more successful. As a young man Godwin had been very much the philosopher -- austere in dress, with an angular figure, an intense manner and piercing glance. While approachable he was not socially adept: he both took offence easily and gave it by his over-commitment to the virtue of candour among friends. Only with his increasing success had he come to meet a wide range of clever women with political, literary and philosophical interests -- such as Helen Maria Williams, Inchbald, Amelia Alderson, Maria Reveley, Mary Hays and Mary Robinson. This contact had its effect. He cut his hair short in 1791 and adopted a less ministerial style of dress, he also enjoyed an increasingly extensive social life (albeit without any indication of self-indulgence) and he even experimented in 1796 with holding a dinner party (which included Parr's daughters, Wollstonecraft, and Inchbald). He also developed a basic competence in flirtation. In the last months of 1795 and first half of 1796, Reveley, Samuel Parr's daughter Sarah, Alderson and Inchbald were all candidates for his attention. Following their re-acquaintance Wollstonecraft called on him, unconventionally, in April 1796, and even though Godwin subsequently met and corresponded with her regularly it was only after being turned down by Alderson in July 1796 that they became closer, becoming lovers in August 1796. Their letters and notes provide a touching record of a philosophical relationship gradually subverted by feelings which Godwin found hard to accommodate and Wollstonecraft hard to trust. Wollstonecraft became pregnant in December and after much deliberation to reconcile their actions to their principles, they married in March 1797. Wollstonecraft's death following childbirth in September 1797 left Godwin distraught and burdened with the care of the baby Mary (later Mary Shelley), Imlay's child Fanny, and a succession of debts. He threw himself into work: he revised *Political Justice* for a third, and final time, wrote a hurried memoir of Wollstonecraft, prepared a collection of her works, and embarked on his second major novel, *St Leon* (1799). Wollstonecraft's influence on Godwin's thinking has been detected by critics in his volume of essays, *The Enquirer* (1798), and in the revisions made for the third edition of *Political Justice*, published at the end of 1797. A rather different sense of their relationship was recorded by him in his *Memoirs of the Author of the Vindication of the Rights of Women* (1798), and in his depiction of marriage in *St. Leon* (1799). The *Memoirs* provoked a storm of controversy by their revelations of Wollstonecraft's unconventional sexual mores. Several of Godwin's past acquaintances

spurned him, he found himself increasingly the subject of attack by loyalist newspapers, and his philosophical opinions were parodied and ridiculed in novels, reviews and pamphlets. Godwin reacted with dignity. His *Thoughts Occasioned by the Perusal of Dr. Parr's Spital Sermon* (1801), sought dispassionately to answer his critics and to confess errors which he now recognised -- and which had already been acknowledged both in the revisions to the later editions of his Enquiry, and in his comments in *St. Leon*. But the reply did little to rescue him from the now overwhelming tide of reaction, and incautious remarks in his discussion of *Malthus' Essay on the Principle of Population* (1798) about exposing children and abortion, were seized upon with glee by the reviewers. Godwin's *Political Justice* was a product of the enthusiasm connected with the French Revolution and by the end of the decade the author and his works were exuberantly denounced by loyalism and the forces of order which increasingly dominated the British political and literary scene. From this point on, for much of the rest of his life, Godwinism became a term of opprobrium. In the new, intolerant political climate Godwin turned to literature and history. He tried his hand at drama with a play, *Antonio* (1800), but with little success; in 1803 he wrote a two volume *Life of Chaucer*; and two years later he produced a further novel, *Fleetwood: or The New Man of Feeling* (1805). To cope with his domestic responsibilities he looked for a new wife, approaching Maria Reveley too soon after the death of her husband, and Harriet Lee who found him too pressing. When a widow with two children, Mary Jane Clairmont, leaned over her balcony in 1801 and asked ‘Is it possible that I behold the immortal Godwin’, his fate was sealed.

In 1805, in an effort to establish his finances on a more secure footing, his friends helped establish him as the proprietor of a children's bookshop. Over the next ten years, writing mainly under the pseudonym Edward Baldwin, Godwin produced a variety of books for children: including collections of fables, myths, and bible stories, histories of England, Rome and Greece, and various dictionaries and grammars, but he wrote little of any real political or philosophical significance for ten years.

In 1814 Godwin's domestic life was thrown into turmoil when Percy Bysshe Shelley eloped to France with Godwin's seventeen-year-old daughter Mary, accompanied by Mary's sixteen year old stepsister, Clare Clairmont. The following decade was marked by repeated family and financial crises, by the suicides of Shelley's first wife, Godwin's stepdaughter Fanny, and of his young protégé Patrickson, and by the deaths of three of Mary Shelley's children, followed hard by the death of Shelley himself in 1822. Yet it was also a productive period for Godwin. His *Lives of Edward and John Philips, nephews of Milton* (1815), his chilling tale of madness, *Mandeville* (1817), and his four volume *History of the Commonwealth* (1824-8) each represent his fascination with the republicanism of the civil war period. He also returned to the subject of education in his *Letters of Advice to a Young American* (1818) and in 1820 he produced a critique of Malthus' *Essay*, which won him some respect in some previously hostile quarters, alongside the undisguised enmity of the *Edinburgh Review*. In the last five years of his life he wrote two further novels, and he returned to the philosophical and terrain of his earlier career in his *Thoughts on Man* (1831), his most sustained piece of philosophy since his *Enquirer* (1798). His final work, unpublished in his lifetime, was a series of essays on Christianity, in which he fulfilled an ambition, first noted in 1798, to "sweep away the whole fiction of an intelligent former world and a future state; to call men off from those incoherent and contradictory dreams, that so often occupy their thoughts, and vainly agitate their fears; and to lead them to apply their whole energy to practical objects and genuine realities." (*Political and Philosophical Writings* (*PPW*) IV, 417). In 1833 Godwin finally

received some recognition when he was given a sinecure post by the then Whig government. Peel's subsequent administration agreed to extend the post until Godwin died in April 1836.

Reputation

Hazlitt famously described Godwin's reputation in the 1790s in an essay in his *Spirit of the Age*: No work gave such a blow to the philosophical mind of the country as the celebrated Enquiry ... Tom Paine was considered for a time as Tom Fool to him, Paley and old woman, Edmund Burke a flashy sophist. Truth, moral truth, it was supposed had here taken up its abode; and these were the oracles of thought.’ Godwin himself confirms the view. When travelling in the Midlands in 1794 he found that ‘I was nowhere a stranger. The doctrines of that work, (his Enquiry Concerning Political Justice) coincided in a great degree with the sentiments then prevailing in English Society, and I was everywhere received with curiosity and kindness.’ (Marshall, *William Godwin*, 121). Six years later, reflecting on his reputation, he wrote,

> I have fallen (if I have fallen) in one common grave with the cause and love of liberty; and in this sense I have been more honoured and illustrated in my decline, than ever I was in the highest tide of my success. (*PPW* II, 165)

Philosophically Godwin's greatest supporters were his contemporaries, such as Thomas Holcroft and John Thelwall, and a younger generation of men (and some literary women) who were attracted to Godwin's intellectual rigour and his radical critique of the social and political order. Many later abandoned him, Coleridge, Wordsworth and Southey as part of a rising tide of loyalist reaction, Shelley and Byron, for more personal and domestic reasons. However, his philosophical keyword>anarchismhad a profound influence on Robert Owen, William Thompson and other utopians in the nineteenth century, and there is also evidence of influence on the Chartist movement and on popular labour movements for political reform in the 1840s (see Marshall, 390). His impact in literary circles was long lasting, both through his political writings, and through his novels. *Political Justice* was read and translated by Benjamin Constant in France, and an abridged edition was translated into German in 1803, along with the first three of Godwin's mature novels. Marx and Engels knew of his work and cited him as having contributed to a theory of exploitation. Later in the nineteenth century Anton Menger and Paul Eltzbacher introduced Godwin's work to German audiences, leading to further translation. Caleb Williams appeared in Russian in 1838, and Chernyshevski, Kroptkin and Tolstoy all read and referred to him. In the late nineteenth century the last Book of *Political Justice*, formally titled ‘Of Property’, but dealing with the prospects for progress in the human race and including his attacks on marriage and co-operation, was reprinted as a socialist tract, and the whole work was reprinted again in the 1920s. A critical edition of the third edition with variants appeared in 1946, and an edition of the 1793 text with both later variants and material from the original manuscripts appeared in 1993. Biographies of Godwin have also appeared regularly since the first by C. Kegan-Paul in 1876, which drew heavily on the extensive manuscript sources. Philosophical interest has been less pronounced, although since the 1940s a slow trickle of books has emerged which have sought to do justice to Godwin's essentially liberal political principles and to his moral philosophy. That work has recognised the importance of thinkers of the French Enlightenment, and more recently the

Dissenting inheritance which his education and early career provided. As a result, the traditional view of Godwin as a strict utilitarian has been increasingly challenged. Recent work in political philosophy on the appropriate form and scope of impartiality has looked to Godwin, most commonly to define a position to resist, but not exclusively so.

Political Philosophy

Godwin's major philosophical treatise is his *Enquiry Concerning Political Justice*. The work went through three editions within 5 years, each with substantial changes. No further edition was published in Godwin's lifetime. Although Godwin's other works shed light on changes in Godwin's position after 1798, *Political Justice* is the most coherent expression of Godwin's political philosophy.

The work began as an attempt to review recent developments in political and moral philosophy, but it quickly became more ambitious in scope:

> In the first fervour of enthusiasm I entertained the vain imagination of ‘hewing a stone from rock’ which by its inherent energy and weight should overbear and annihilate all opposition, and place the principles of politics on an unmoveable basis. (*CNM* I, 49)

The discarded first draft centres on the work of Montesquieu and Raynal, while the published work abandons the expository mode and develops its own independent line of argument. Godwin begins by defending the importance of political inquiry and refuting claims that moral and political phenomena are a function of climate, national character or luxury. He argues that character is a function of experience and that the type of government under which people live has an overwhelming impact upon their experience -- bad government produces wretched men and women. Although he is initially prepared to endorse the *philosophe* and republican view that government can have a positive impact on the development of virtue, this view is soon set aside in favour of the argument that moral and political improvement flows from progress in our understanding of moral and political truth -- a process to which there is no limit.

Book Two examines the basic principles of human society, equality, rights, justice, and private judgment. Godwin follows Paine's view in *Common Sense*, that "society is in every state a blessing...government even in its best state is but a necessary evil" (*PPW* III, 48), by seeing society as antecedent to government with its principles setting the bounds of its legitimacy. The basic moral principle is that of justice:

> If justice have any meaning, it is just that I should contribute everything in my power to the benefit of the whole. (*PPW* III, 49)

This principle is filled out by two further principles. The first, equality, is used to establish that we are beings of the same nature, susceptible of the same pleasures and pains, and equally endowed with the capacity for reason. This is to endorse the philosophe principle that birth and rank must not affect the way people are treated -

> the thing really to be desired is the removing as much as possible arbitrary distinctions, and leaving to talents and virtue the field of exertion unimpaired (*PPW* III, 65).

But he also believes (as in the Fénelon case) that some have a higher moral value than others. This second judgment seems rigorously consequentialist, in that we value them more if and only if they contribute more to the general good (a position in line with Godwin's rejection in Book Seven of all desert-based accounts of punishment). Tensions are introduced into his account, however, by the emphasis he places on intention in assessing a person's action -

> It is in the disposition and view of the mind, and not in the good which may accidentally and inintentionally result, that virtue consists. (*PPW* III, 193)

and by his characterisation of the ideal agent as someone devoted to a life of benevolence and virtue. In both instances he appeals to a agent-centred account of virtue, more than to a consequentialist account, and in doing so acknowledges a form of moral worth which is not wholly reducible to consequentialist considerations. The second principle to which he appeals, the doctrine of private judgment, is advanced as the logical complement to the principle of justice:

> to a rational being there is but one rule of conduct, justice, and one mode of ascertaining that rule, the exercise of his understanding. (*PPW*, III, 72).

Here again, although Godwin appeals in part to consequentialist considerations to ground a duty to private judgment, it also plays an integral part of his conception of what it is to be a fully rational agent. When combined with the principle of equality, the principle of private judgment issues in a basic constraint on certain types of consequentialist intervention - each person acts morally only in so far as each acts wholly on the dictates of his or her private judgment. To effect real improvement we must work by appealing to the rational capacities of each of our fellow citizens.

Book Three and the first part of Book Four develop Godwin's case against existing theories of government, in each case making his case by drawing on his opening argument that there is no intrinsic limit on the development of human understanding and enlightenment. The philosophical underpinning for this argument is given in the second half of Book Four where Godwin examines the character of truth and its relationship to virtue and goes on to discuss arguments relating to freedom of the will, the doctrine of philosophical necessity, and the character of moral motivation. He shows that men are capable of recognising truth, and that, because mind acts as a real cause, they will act on it when they perceive it clearly. Nothing beyond the perception of truth is required to motivate our compliance with moral principles. It is this which justifies the description of Godwin's position as ‘rationalist’, and it is on ths point - the motivating power of reason - that later editions show a degree of retraction. One possible source for the position is Richard Price's *Reiview of the Principal Questions of Morals* (1756, but it is noteworthy that Godwin himself later identified this ‘error’ as a function of his Sandemanianism. In *Political Justice*, however, Godwin builds his argument on foundations laid by David Hartley and Joseph

Priestley, albeit he develops their position by insisting that mind is the medium within which sensations, desires, passions and beliefs contend -- so that we should understand the conflict between passion and reason as one of contending opinions. Such contention can be assessed impartially by the mind which will assess the true value of each claim and act on the judgment.

Books Five to Eight apply the principles of justice, equality and private judgment in a critical examination of the institutions of government, issues of toleration and freedom of speech, theories of law and punishment, and, finally, the institution of property. In each case, government and its institutions are shown to constrain the development of our capacity to live wholly in accordance with the full and free exercise of private judgment. In the final book Godwin sketches his positive vision of the egalitarian society of the future, one which, having dispensed with all forms of organised co-operation, including orchestras and marriage, so as to ensure the fullest independence to each persons' judgment, will gradually witness the development of the powers of mind to the point that they gain ascendancy over physiological process allowing life to be prolonged indefinitely.

In 1800 Godwin wrote:

> The Enquiry concerning Political Justice I apprehend to be blemished principally by three errors. 1. Stoicism, or an inattention to the principle, that pleasure and pain are the only bases upon which morality can exist. 2. Sandemanianism, or an inattention to the principle that feeling, and not judgment, is the source of human actions. 3. The unqualified condemnation of the private affections. It will easily be seen how strongly these errors are connected with the Calvinist system, which had been so deeply wrought into my mind in early life, as to enable these errors long to survive the general system of religious opinions of which they formed a part...The first of these errors...has been corrected with some care in the subsequent edition of Political Justice. The second and third owe their destruction to a perusal of Hume's *Treatise of Human Nature* in the following edition. (*CNM*, I, 54)

This account is a fair characterisation of the changes which Godwin made in the second and third editions. Sentiment and feeling are given a much more powerful role, no longer to be expunged by the power of truth; the private affections are allowed to play a part in moral reasoning; and a more consistently utilitarian language is deployed throughout the work. As a consequence, the rationalism which marked the first edition becomes muted and, while the belief in progress is maintained, the more utopian flights of the first edition are omitted.

Moral Philosophy

One of the most powerful attacks on Godwin was that made in Dr. Samuel Parr's ‘Spital Sermon’ of 1800. It was Godwin's advocacy of universal benevolence against which Parr directed his energies, centring his attack on Godwin's early dismissal of family feeling, gratitude and various natural sentiments. For Godwin, these are passions unconstrained by judgment, and so should not play a role in determining how we should act. He exemplifies his case in what has come to be known as the ‘Famous

Fire Cause', in which the reader is asked to imagine being able to save only one of two people in a fire, one of whom is the Archbishop Fénelon, a benefactor to the whole human race, the other of whom is the reader's parent (mother in the first edition, father thereafter!). Godwin's view is that justice demands that we act impartially for the greater good, which means saving Fénelon. He never abandoned this case, nor the view that it is our duty to act to bring about the greatest good. Just as a judge should not be influenced by familial or private concerns in his judgment, so too is the moral agent bound to judge impartially. In replying to Parr, Godwin expresses regret that he had not appealed to the still more persuasive case of Brutus executing his two sons -- a striking example, and a republican commonplace about justice trumping paternal duties. As Godwin says, saving someone just because they are a relation seems bizarre without some additional judgment about their moral worth: a parent who is foolish or evil cannot have an over-riding claim on us against the moral deserts of all other members of the human race. That position, Godwin retains. Moreover, in his reply to Parr, he insists that these extraordinary cases are unlikely to shake the domestic affections in the ordinary intercourse of life. However, from the later editions and other works, it becomes clear that he will admit, in the more normal course of events, a much more substantial role to be played by our natural affections and attachments. They provide us both with information about how best we might benefit others, and a basic moral motivation which can be relied on in normal cases and which can be generalised beyond the narrow domestic sphere (a position much indebted to Adam Smith's *Theory of Moral Sentiments*). These changes are significant: it leaves us a less rationalist, more philosophically robust, account of moral motivation and its relationship to the principle of utility, and it does much to moderate the utopianism of the first edition.

The impact of these changes on Godwin's over-all position is more difficult to assess. What we see in the changes is a consistent shift away from the rationalist account of moral motivation which marked the first edition to a position which is much more sceptical about the power of reason. This scepticism inevitably moderates Godwin's belief in perfectibility, since it becomes more difficult to argue for convergence on principles of morality and the progressive development of knowledge. It also inevitably undermines Godwin's faith in the triumph of mind over physiological processes. That said, neither the doctrine of private judgment nor the principle of utility depend on his earlier rationalism. The former is defended by Godwin on the grounds that only free action has moral value, and that the fullest possible exercise of private judgment is required for one's actions to be free - further evidence of Godwin's attempt to provide an agent-centred account of virtue alongside his consequentialism. With this commitment private judgment remains defensible even if there is a low probability that its exercise will produce true beliefs, so long as no other better method of tracking truth is available (which also becomes proportionately less likely as one's scepticism increases). The defence might require that cognitive status be attributed to moral judgments, but it might also be possible to sustain the argument for private judgment independent of the issue of ethical objectivity. The utility principle might seem to call for an ability to make sound ethical judgments in complex situations but, again, if we are sceptical about people's ability to judge well, this does not entail (and seems to deny) that there is a better way of judging. On both counts then, Godwin's central principles remain intact despite the changes he makes to the account of moral motivation and judgment. Moreover, Godwin's view of man's progressive character might be defended by placing greater weight on the baleful effects of the social and political institutions of the European aristocracies than on the epistemological dimensions of the account.

However, Godwin's endorsement of both the principle of utility as the sole guide to moral duty and the principle of private judgment as a block on the interference of others, is not without tensions. His consistent doctrine is a combination of these two principles: that it is each individual's duty to produce as much happiness in the world as he is able, and that each person must be guided in acting by the exercise of his private judgment, albeit informed by public discussion. If the resulting doctrine is utilitarian it is a highly distinctive form: it is act-utilitarian in that it discounts reliance on rules (although see Barry's suggestion that his act- utilitarianism gives way to motive utilitarianism, *Justice as Impartiality* 224; and see Godwin's invocation of sincerity as a partial rule constraint in the first edition, PPW III, 135-42); it is ideal, in that it acknowledges major qualitative differences in the pleasures; and it is indirect, in that we can only promote over-all utility by improving the understanding of our fellow human beings. More troubling to the view that this none the less amounts to utilitarianism is Godwin's insistence on private judgment as a basic constraint, and his associated characterisation of the fully moral agent in terms of the full development of the individual's intellectual powers and potential. Indeed, Godwin's account of pleasure, in terms of the development of intellect and the exercise of its powers, means that the position looks as much like perfectionism as it does a form of hedonistic utilitarianism (what is valued is the ideal as much as the pleasures which are integral to it). Furthermore, it suggests that no distincton can be drawn between the means which we adopt to promote the general good and the character of the general good itself. That is, what promotes the general good is the development of human intellect, but the general good just is the development of the human intellect. If that is true, Godwin's account cannot be utilitarian because it cannot be consequentialist (because it cannot separate the means to the end from the end which is sought).

Such issues of interpretation remain very much in dispute in studies of Godwin (compare Clarke (1977) with Philp (1986)), complicated by issues concerning the weight to be given to the different editions of *Political Justice* and Godwin's later writings. However, even if a utilitarian reading of Godwin is accepted, it remains the case that the doctrine is strictly a precept of individual moral judgment. Because of his broader views as to the corrupting influence of government, there can be no extension of the principle to politics. Each of us must judge as best we can how to advance the good of all, but every person is owed a respect for their private judgment which precludes us from exercising authority over them. By this constraint, Godwin delivers utilitarianism from the more statist approaches of Bentham and later utilitarians. It also ensures that the doctrine retains a fundamentally egalitarian form. The constraint also supports the view that Godwin reached his philosophical position less through the *philosophes*, than by secularising Dissenting arguments for the sanctity of private judgment and generalising their application to every mode of human activity. This commitment also provides support for a reading of Godwin's position which sees it as concerned with individual moral perfectibility, couched in the language of utility, rather than as strictly utilitarian.

A Philosophy of History

Political Justice condemns all government interference with individual judgment. He claims that over time history has seen gradual progress as knowledge has developed and has spread and as men and women have liberated themselves from their political chains and their subordination to the fraud and

imposture of monarchical and aristocratic government and established religion. His optimistic belief in the impotence of government against advancing opinion (which partly glosses and extends Hume's comment that all government is founded on opinion) is balanced by some sociologically perceptive comments on the baleful influence that certain types of political power have on those who exercise it or are subject to it. These insights are also explored in The *Enquirer*, but it is in Godwin's later novels, from *Caleb Williams* (1794) onward, that it is given its fullest rein. As Godwin indicates in his unpublished essay, ‘On History and Literature’ (1798) (*PPW* V, 290-301), literature can be used to show how the cultures and institutions into which we are born come inexorable to shape our lives, leading us to act in ways which destroy our chances of happiness. The six mature novels effectively follow through the critical enterprise launched in *Political Justice* by their narrative histories of men who are brought to grief by the aristocratic and inegalitarian principles of their societies.

Bibliography

Primary Sources

A complete bibliography of Godwin's work published in his lifetime is given in volume 1 of *The Collected Novels and Memoirs of William Godwin* 8 Volumes ed., Mark Philp (London, Pickering and Chatto, 1992) and in volume 1 of *The Political and Philosophical works of William Godwin*, 7 Volumes ed., Mark Philp, (London, Pickering and Chatto, 1993). These are referred to below as, respectively *CNM* and *PPW*.

- *History of the Life of William Pitt, Earl of Chatham* printed for the Author and sold by G. Kearsley, published anonymously, (London, 1783). (See *PPW* I)
- *An Account of the Seminary that will be opened on Monday the Fourtb Day of August at Epsom in Surrey*, published anonymously, (London, T. Cadell, 1783). (See *PPW* V)
- *Sketches of History in Six Sermons*, (London, T. Cadell, 1784) 190. (Some copies anonymous, others with Godwin's name) (See *PPW* VII).
- *The Herald of Literature, as a Review of the most considerable publications that will be made in the course of the ensuing Winter*, published anonymously, (London, J. Murray, 1784). (See *PPW* V)
- *Instructions to a Statesman. Humbly inscribed to the Right Honourable George Earl Temple*, published anonymously, (London, Murray, J. Debrett & J. Sewell, 1784). (See *PPW* I)
- *An Enquiry concerning Political Justice, and its Influence on General Virtue and Happiness*, 2 volumes, (London, G. G. & J. Robinson, 1793) 4o, xiii, 378, 379-895. A pirated first edition also published 2 volumes 8o in Dublin by Luke White, 1793, xiii, 411, 424. Copies of the octavo first edition with a Robinson flyleaf also exist. 2nd edition, 2 volumes 8o, (London, Robinson, 1796), xviii, 464, v, 545; 3rd edition, 2 volumes 8o, (London, Robinson, 1798), lvi, 463, ix, 554. See also *Enquiry Concerning Political Justice*, 3 volumes, ed., F. E. L. Priestley, (Toronto, University of Toronto Press, 1946, 1969). Facsimile reprint of the third edition with variants from the first and second editions in volume 3; *Enquiry Concerning Political Justice*, ed., Isaac Kramnick (Harmondsworth, Penguin Press, 1976), 825 (third edition); and *PPW* III and IV (first edition text

plus variants from manuscript and from the subsequent editions).

- *Things As They Are; or The Adventures of Caleb Williams*, 3 volumes, (London, B. Crosby, 1794). Critical edition of the fifth edition edited by D. McCracken, Oxford University Press, 1970. Critical edition of the first edition in *CNM* III.
- *Cursory Strictures on the Charge delivered by Lord Chief Justice Eyre to the Grand Jury ... October 2, 1794, first published in the Morning Chronicle October 21*, Published anonymously, (London, D. I. Eaton, 1794) and *A Reply to an Answer to Cursory Strictures, supposed to be wrote by Judge Buller. By the Author of Cursory Strictures*, published anonymously, (London, D. I. Eaton, 1794), 7. (See *PPW* II)
- *Considerations on Lord Grenville's and Mr. Pitt's Bills, concerning Treasonable and Seditious Practices, and Unlawful Assemblies*. By a Lover of Order, published anonymously, (London, J. Johnson, 1795), 86. (See *PPW* II).

Collected Works

- *Collected Novels and Memoirs of William Godwin*, 8 volumes, ed., Mark Philp, London, Pickering and Chatto Publishers Ltd., 1992. A complete scholarly edition of all Godwin's published novels, his biography of Mary Wollstonecraft, and a range of previously unpublished autobiographical writings. Caleb Williams and Memoirs of the Author of the Vindication of the Rights of Woman are set in the first edition with variants from later editions (and, for Caleb Williams, the manuscript) given in an appendix. All other novels are set from the last edition published within the author's lifetime.
- *Political and Philosophical Writings of William Godwin*, 7 volumes, ed., Mark Philp, London, Pickering and Chatto Publishers Ltd.,1993. A scholarly edition of Godwin's principal writings in politics, philosophy, education and theology, including previously unpublished manuscript material. The edition is made up of two volumes of Godwin's principal political essays, including a substantial unpublished essay; two volumes of his Enquiry Concerning Political Justice, which is set in the first edition (volume III) with variants from the manuscript and the second and third editions given in volume IV (volume IV also includes a previously undiscovered first draft of the Enquiry together with manuscript material relating to the publication of and revisions to the Enquiry); the three later volumes collect Godwin's main educational and literary writings, with previously unpublished material (Volume V), his later essays (volume VI) and his religious writings, including unpublished material and a re-edited edition of Godwin's last,unfinished work, The Genius of Christianity Unveiled (volume VII).
- *Four Early Pamphlets (1783-1784)*, ed., B. R. Pollin, (Gainsville, Florida, Scholars' Facsimiles and Reprints, 1966).
- *Uncollected Writings (1785-1822)*, ed. J. E. Marken and B. R. Pollin, (Gainsville, Florida, Scholars Facsimiles and Reprints, 1968)

Manuscript Collections

- Bodleian Library, Oxford. The Abinger collection, owned by Lord Abinger is a very extensive holding of Godwin's manuscript material, correspondence and diaries. Some of the earlier deposits were microfilmed by Duke University but there have been several deposits made subsequently.
- National Art Library, Victoria and Albert Museum, London. The Forster/Dyce Collection includes the manuscripts to Godwin's Political Justice, Caleb Williams, Life of Chaucer and History of the Commonwealth, and a limited amount of correspondence.
- Pforzheimer Library, New York. Contains the manuscript of Fleetwood and miscellaneous correspondence and material relating to St Leon. (It has been edited by K. N. Cameron, Shelley and his Circle ,volumes I-IV, Cambridge, Mass., Harvard University Press, 1961-70, and D. H. Reiman, volumes V-VI, Ibid., 1973.

Lord Shaftesbury [Anthony Ashley Cooper, Third Earl of Shaftesbury]

Anthony Ashley Cooper, the third Earl of Shaftesbury, lived from 1671 to 1713. He was one of the most important philosophers of his day, and exerted an enormous influence throughout the eighteenth and nineteenth centuries on British and European discussions of morality, aesthetics and religion.

Shaftesbury's philosophy combined a powerfully teleological approach, according to which all things were part of a harmonious cosmic order, with sharp observations of human nature (see section 2 below). Shaftesbury is often credited with originating the moral sense theory, although his own views of virtue are not as thoroughly anti-rationalist as those of later sentimentalists such as Hutcheson and Hume (section 3). While he argued that virtue leads to happiness (section 4), Shaftesbury was also a fierce opponent of psychological and ethical egoism (section 5) and of the egoistic social contract theory of Hobbes (section 6). Shaftesbury's view of aesthetic judgment was both sentimentalist and objectivist, in that he thought that correct moral judgment was based in human sentiments that reflected accurately the harmonious cosmic order (section 7). Shaftesbury's belief in an harmonious cosmic order also dominated his view of religion, which was based on the idea that the universe clearly exhibited signs of divine design (section 8); according to Shaftesbury, the ultimate end of religion, as well of virtue, beauty and philosophical understanding (all of which are turn out to be one and the same thing), is to identify completely with the universal system of which one is a part.

1. Shaftesbury's Life and Works

Shaftesbury lived from 1671 to 1713. His grandfather, the first Earl of Shaftesbury, oversaw Shaftesbury's early upbringing, and put John Locke in charge of his education. Shaftesbury would eventually come to disagree with many aspects of Locke's philosophy (such as the latter's empiricism, his social contract theory, and what Shaftesbury perceived to be his psychological and ethical egoism), but Locke was clearly a crucially important influence on Shaftesbury's philosophical development, and the two men remained friends until Locke's death.

Shaftesbury served in Parliament and the House of Lords, but ill health curtailed his political career when he was 30 years old. From then on, he concentrated most of his energies on his philosophical and literary writings.

The first work Shaftesbury published was an edited collection of sermons by Benjamin Whichcote, which came out in 1698. Shaftesbury wrote an unsigned preface to the sermons in which he praised Whichcote's belief in the goodness of human beings and urged his readers to use Whichcote's "good nature" as an antidote to the poisonous egoism of Hobbes.

In 1699, John Toland published an early version of Shaftesbury's *Inquiry concerning Virtue*. But Shaftesbury renounced this version of the Inquiry, claiming (probably truthfully) that it was produced without his authorization.

Most of the works for which Shaftesbury is famous were written between 1705-1710. It was during this period that he rewrote the *Inquiry concerning Virtue* and completed versions of *A Letter concerning Enthusiasm*, *Sensus Communis: An Essay on the Freedom of Wit and Humour, The Moralists and Soliloquy, or Advice to an Author*.

In 1711, he collected his mature works into a single volume and added to them extensive notes and commentary, naming the book *Characteristics of Men, Manners, Opinions, Times*. He revised the *Characteristics* over the course of the next two years, up until his death in 1713. A revised edition came out in 1714.

The *Characteristics* is a remarkable volume. It covers a great many topics, ranging freely over morality, art, politics, religion, aesthetics, culture and politeness, and it is written in many different styles, including epistles, soliloquys, dialogues and treatises. The overarching goal of the book, as Klein has put it in his very helpful introduction, is to make its readers "effective participants in the world" (*Characteristics* viii). Shaftesbury saw the *Characteristics* as an exercise in practical (and not merely speculative) philosophy -- as a work that would enable people to live better lives.

The *Characteristics* was extremely popular in Britain and Europe throughout the eighteenth and nineteenth centuries. It was a book that was closely studied by numerous philosophers and artists, as well as widely read by educated people in general.

In addition to the Characteristics, there are two other major posthumous collections of Shaftesbury's writings: the *Second Characteristics,* which is concerned chiefly with the visual arts, and his philosophical notebooks, which Rand has collected in The Life, Unpublished Letters and Philosophical Regimen of Anthony, Earl of Shaftesbury. The notebooks are particularly interesting, as they offer a view of Shaftesbury's private ruminations and of his profound commitment to elements of stoicism.

2. Shaftesbury's View of Human Nature: Teleology and Observation

Shaftesbury's view of human nature is both teleological and observation-based. Indeed, he believes that teleology and observation must go hand-in-hand -- that accurate observation of human psychology requires a teleological conception of humanity, and that one needs to observe human beings to learn about the human telos. He is very critical of philosophers who examine human beings without placing their findings within a teleological context, comparing them to someone who examines the individual parts of a watch without taking into account the purpose for which the watch was designed: just as the latter person will never really come to a proper understanding of the watch, Shaftesbury argues, so too the former will never come to a proper understanding of human nature. Shaftesbury thought that Descartes and Locke were guilty of this narrow non-teleological type of philosophizing.

3. Moral Sentimentalism and Moral Rationalism

Shaftesbury, like most teleologically-minded philosophers, contends that the end or telos of human nature is virtue, and much of his writing is devoted to an explication of his conception of virtue. The account of virtue Shaftesbury proposes has often been taken to be the origin of moral sentimentalism or the moral sense theory, which Hutcheson and Hume would later develop. But while there are parts of Shaftesbury's account of virtue that are undeniably sentimentalist, there are also rationalist elements that defy the sentimentalist or moral sense label. Let us first note the most conspicuously sentimentalist aspects of Shaftesbury's view, and then note the more rationalist aspects.

The place in Shaftesbury in which the moral sense theory most clearly begins to take shape is his *Inquiry concerning Virtue or Merit*, Book I, Part II, Section 3, where he explains his view of "virtue or merit." When other beings "offer themselves" to our senses, Shaftesbury explains in that section, we perform actions and feel affections. So much we have in common with other animals. But we humans also consider our own actions and affections, and form affections about them. As Shaftesbury puts it, "[T]he very actions themselves and the affections of pity, kindness, gratitude and their contraries, being brought into the mind by reflection, become objects. So that, by means of this reflected sense, there arises another

kind of affections towards those very affections themselves, which have been already felt and have no become the subject of a new liking or dislike" (*Characteristics of Men, Manners, Opinions, Times*, edited by Lawrence Klein [Cambridge: Cambridge University Press, 1999], 172).

This reflected sense, Shaftesbury contends, is the origin of virtue, by which he means both that a being can form a judgment about what is virtuous and vicious only if it has this reflected sense, and that a being can be judged virtuous and vicious only if its actions are influenced by its own reflected sense.

> So that if a creature be generous, kind, constant, compassionate, yet if he cannot reflect on what he himself does or sees others do so as to take notice of what is worthy or honest and make that notice or conception of worth and honesty to be an object of his affection, he has not the character of being virtuous. For, thus and no otherwise, he is capable of having a sense of right or wrong, a sentiment or judgment of what is done through just, equal and good affection or the contrary. (*Characteristics* 173)

These passages from Book I, Part II, Section 3 of the Inquiry seem to give us all we need to attribute to Shaftesbury a sentimentalist or moral sense view or virtue. The fact that Shaftesbury attributes to humans a "sense of right or wrong" is not on its own enough to make the attribution, since that phrase is general enough to refer to a rational capacity as well as a sentimentalist one. But earlier in the section Shaftesbury has called the response from which virtue originates an "affection" and a "liking or dislike." He has also maintained that the response that is essential to virtue is similar to (or perhaps the same as) the "heart"-based pleasure we feel when we see or hear something beautiful. Later in the *Inquiry*, moreover, Shaftesbury says that "this sense of right and wrong ... must consist in a real antipathy or aversion to injustice or wrong and in a real affection or love towards equity and right" (*Characteristics* 178). And in the passage quoted above from *Characteristics* 173, he seems to equate moral judgment with "a sentiment." All of this looks to be conclusive evidence that at the core of Shaftesbury's view of morality is something emotional, sentimental or passionate -- not rational.

Further evidence of a sentimentalist moral theory in Shaftesbury occurs in his discussion of how a person can come to lose his sense of right and wrong. He argues (in a manner that anticipates Hume) that because our sense of morality is a sentiment, it can be opposed only by another sentiment, and not by reason or belief. "Sense of right and wrong," he writes, "therefore being as natural to us as natural affection itself, and being a first principle in our constitution and make, there is no speculative opinion, persuasion or belief which is capable immediately or directly to exclude or destroy it... [T]his affection being an original one of earliest rise in the soul or affectionate part, nothing beside contrary affection, by frequent check and control, can operate upon it so as either to diminish it in part or destroy it in the whole" (*Characteristics* 179).

There are other passages, however, in which Shaftesbury sounds a more rationalist note. He speaks, for instance, of the "eternal measures and immutable independent nature of worth and virtue" (*Characteristics* 175) and of "a fitness and decency in actions" (*Characteristics* 327) -- phrases that are touchstones for the rationalists of the period and which Hutcheson and Hume would later attack. And he

contends that "partial affection, or social love in part, without regard to a complete society or whole, is in itself an inconsistency, and implies an absolute Contradiction," as well as maintaining that an affection that is "applied only to some one part of society, or of a species, not to the species of society itself ... has no foundation or establishment in reason" (*Characteristics* 205). Moreover, Shaftesbury often links worth and virtue to a "universal system" (*Characteristics* 167-170) yet another idea that Hutcheson and Hume would eschew.

How are the rationalist-sounding passages in Shaftesbury to be reconciled with his sentimentalist-sounding ones? Shaftesbury seems to think that value exists independently of human affections but that our affections are what enable us to make value judgments (which in turn is what makes us capable of virtue or merit). Shaftesbury's "sense of right and wrong" is, then, truly a sentiment, but it is a sentiment that accurately represents an objective reality -- i.e., a reality that is independent of human sentiments. Shaftesbury tells the same story about aesthetics: there is, he maintains, an eternal and immutable standard of beauty, one that is independent of human affections, but our affections are what enable us to learn about beauty and make aesthetic judgments.

Does this combination of rationalism and sentimentalism constitute a coherent view? Butler might have thought so, and it's just possible that Hutcheson did as well (although Hutcheson's views of this matter are very difficult to pin down). But Balguy, Hume and most twentieth century meta-ethicists would contend that all of Shaftesbury's statements about morality cannot be consistently combined with each other -- that something has to go. However that may be, it is worth keeping in mind that Shaftesbury himself was probably unconcerned about the problem of reconciling aspects of moral rationalism with aspects of moral sentimentalism. This is partly due to the fact that the sharp distinction between rationalism and sentimentalism had not yet been drawn at the time at which Shaftesbury was writing. It is also partly due to the fact that Shaftesbury did not have as a goal for all of his writings the construction of a single systematic theory. His underlying purpose was to improve the character of his readers, and toward this end he was quite willing to write in different styles and different voices, and to use different arguments from one writing to the next. That is not to say that Shaftesbury was happy to contradict himself. But he did seem to think that one could advance the cause of virtue in different ways and that a strict adherence to systematic rigor could frustrate the higher ends to which philosophy should be put.

4. Virtue and Happiness

One point on which Shaftesbury never wavers is that virtue promotes the good of all humankind. As he says, "To love the public, to study universal good, and to promote the interest of the whole world, as far as lies within our power, is surely the height of goodness" (*Characteristics* 20). Or as he puts it elsewhere, the virtuous person is the one who strives to develop an "equal, just and universal friendship" with all humankind. This view of the content of virtue -- that to be virtuous is to promote the good of all humankind -- fits well with Shaftesbury's teleological approach. For he believes that every thing is designed to promote the good of the system of which it is a part. And he also believes that every human being is a part of the system that is the human species as a whole. It is natural for him to think, therefore, that every human being is designed to promote the good of the human species as a whole. (It is important

to note, however, that this view of a system and its parts explains only Shaftesbury's view of the content of goodness, which is something that non-human can also attain. Virtue or merit, which humans alone can attain, involves not merely acting for the good of the system but performing such actions in a self-aware or reflective manner.)

Shaftesbury also consistently maintains that in addition to promoting the good of humanity, virtue promotes the happiness of the virtuous person him or herself, just as vice harms humanity as a whole as well as making the vicious person unhappy. On Shaftesbury's view, in other words, "virtue and interest may be found at last to agree" (*Characteristics* 167). Or as he puts it in the conclusion of the *Inquiry*, "And thus virtue is the good and vice the ill of everyone" (*Characteristics* 229-330). The coincidence of virtue and happiness is just what Shaftesbury's teleological approach should lead us to expect. For teleological thinking generally includes the idea that the best life for a being is one that fulfills the being's natural end or purpose, and being virtuous is the end or purpose for which humans were designed.

Shaftesbury corroborates this teleological connection between virtue and happiness by investigating the pleasures and pains of which human happiness and unhappiness consist. He begins this investigation by drawing a broad distinction between pleasures of the body and pleasures of the mind. He next contends that a person's happiness depends more on mental pleasures than on bodily pleasures. And he then seeks to show that living virtuously is by far the best way to gain the crucially important mental pleasures. Shaftesbury bases much of his "mental pleasures" argument for the connection between virtue and happiness on the idea that the mental pleasures are within one's own control, insulated from the vicissitudes of "fortune, age, circumstances and humour." As one of Shaftesbury's characters rhetorically asks, "How can we better praise the goodness of Providence than in this, 'That it has placed our happiness and good in things we can bestow upon ourselves'?" The importance Shaftesbury places on our control over our mental pleasures grows directly out of his appreciation for the Stoics. And indeed, it can be plausibly maintained that Stoicism is one of the strongest and most fundamental commitments of Shaftesbury's thought overall.

5. Attacks on Egoism

But although Shaftesbury believes that being virtuous makes a person happy, it would be wrong to label him an egoist. In fact, he launches many attacks on both psychological egoism and ethical egoism, attacks that have as their main target Hobbes and which clearly anticipate the influential anti-egoist arguments in Butler, Hutcheson and Hume.

Shaftesbury argues, first of all, that psychological egoism does a simply terrible job of explaining the wide spectrum of observable activities humans engage in. He ridicules, for instance, egoistic interpretations of things as "civility, hospitality, humanity towards strangers or people in distress," maintaining that it is much easier to explain such phenomena simply by positing real sociability and benevolence. He also points out that humans are often motivated by "caprice, zeal, faction and a thousand other springs, which are counter to self-interest" and suggests that the only way psychological

egoism can be plausibly maintained is at the expense of becoming tautologous.

Against ethical egoism, Shaftesbury argues that virtue can exist only if it's possible for people to be motivated by something other than self-interest. For a person's virtue, according to Shaftesbury, consists not of the actions he performs but of the motives he has for performing them. And the motive with which we identify virtue is benevolence, not self-interest. Shaftesbury emphasizes this point by drawing attention to the difference between a knave and a saint. We judge the saint virtuous, he explains, because we think he is motivated by something other than the selfishness of the knave. And if we came to believe that the saint's motive were mere selfishness, we would no longer judge him to be virtuous. As he puts it, "If the love of doing good be not of itself a good and right inclination, I know not how there can possibly be such a thing as goodness or virtue"(*Characteristics* 46).

Shaftesbury's belief that true virtue must flow from non-egoistic motives leads him to criticize sharply the emphasis many religious moralists place on reward and punishment in the afterlife. As one of his characters explains when summarizing the goal of the Inquiry, "[The author of the *Inquiry*] endeavors chiefly to establish virtue on principles by which he is able to argue with those who are not as yet induced to own a god or future state. If he cannot do thus much, he reckons he does nothing" (*Characteristics* 266). Shaftesbury eschews considerations of the afterlife in his case for virtue because he believes that persons who perform virtuous actions only because they desire reward and fear punishment have no real virtue in them at all. And persons who are constantly made to dwell on reward and punishment are likely to become overly concerned with their own "self-good and private interest," which must "insensibly diminish the affections towards public good or the interest of society and introduce a certain narrowness of spirit" (*Characteristics* 184). So an emphasis on reward and punishment cannot make people more virtuous, and it may very well make them less so (*Characteristics* 45-46).

Shaftesbury's anti-egoistic view also leads him to an interesting consideration of what we should say to someone who asks for a reason to be virtuous when he knows he will not be punished for vice, or, as Shaftesbury puts the question, "Why should a man be honest in the dark?" (*Characteristics* 58). At times Shaftesbury suggests that a person who asks this question is already lost to virtue -- that someone who cares about virtue for its own sake won't need another reason to act virtuously, and that someone who needs another reason doesn't have what it takes to be truly virtuous in the first place. At other times, Shaftesbury suggests that we should be honest even in the dark (i.e., virtuous even when we will not be punished for vice) because such conduct is a necessary condition for having a unified self at all (*Characteristics* 127). These suggestions of how to deal with the question "Why be moral?" are almost certainly antecedents of Hume's response to the sensible knave at the end of his *Enquiry concerning Morals*.

6. Attacks on Social Contract Theory

Another point on which Hume seems to be indebted to Shaftesbury is criticism of social contract theories. Shaftesbury argues the selfish beings Hobbes describes in his state of nature bear no

resemblance to humans as they actually are. For naturally, Shaftesbury contends, humans are sociable. And society is thus humankind's natural condition. "In short, if generation be natural, if natural affection and the care and nurture of the offspring be natural, things standing as they do with man and the creature being of that form and constitution he now is, it follows that society must be also natural to him and that out of society and community he never did, nor ever can, subsist" (*Characteristics* 287). Shaftesbury also argues that if Hobbes's description of an amoral state of nature were correct, then it would be impossible for Hobbes ever to establish a duty to obey the laws of society. For if there is no duty to keep one's promises in the state of nature, then the original contract cannot create a duty. And if the original contract does give rise to a duty, then there must have been a duty to keep one's promises even in the state of nature (*Characteristics* 51). Shaftesbury was not the first to criticize social contract theories in this way, but his version of this criticism is stated very clearly and was probably among the most influential.

7. Aesthetics

Shaftesbury's views on aesthetics were also very influential in the eighteenth and nineteenth centuries. The conception of beauty Shaftesbury proposes is very similar to his conception of virtue. Indeed, Shaftesbury contends that proper taste in morals and proper taste in art turn out to be much the same thing, and that this is because the beautiful and the good ("natural beauty" and "moral beauty" [*Characteristics* 65]) are themselves "one and the same" (*Characteristics* 330). Or as he puts it elsewhere, "Thus are the arts and virtues mutually friends and thus the science of virtuosos and that of virtue itself become, in a manner, one and the same" (*Characteristics* 150). Shaftesbury believes that we judge beauty through our affections, but that the beautiful itself is not dependent upon our affections. There is, he contends, a real aesthetic standard that is affection-independent. And what we must do is try to develop and improve our affections in order to acquire taste that is in line with that real aesthetic standard -- just as we must try to develop and improve our affections in order to acquire a character in line with the reality of virtue. Shaftesbury's teleology is crucial to his aesthetics as well, in that he equates beauty with the harmony of the universe. "For all beauty is truth" (*Characteristics* 65). In addition to these general aesthetic claims, Shaftesbury makes a great many specific stylistic points about literature, criticism, music and the visual arts.

8. Religion

Although he resisted complete identification with them, Shaftesbury's religious views share much with the English Deists, and he, like them, was a strong proponent of natural religion. Shaftesbury repeatedly advances versions of the argument from Design for the existence of God, and his general teleological approach is deeply theistic (it could perhaps be said that his teleology and his religion were one and the same thing). At the same time, Shaftesbury places little stock in the institutions and rituals of organized religion, and he maintains that the Scriptures are not self-verifying but must always submit to the judgment of our natural understanding. Shaftesbury argues that a truly religious frame of mine -- a frame of mind attuned to the harmonious workings of the universe as a whole -- bolsters one's commitment to virtue. But he also maintains that an atheist can be virtuous, and that bad religion is more destructive to

virtue than no religion at all. Shaftesbury criticized certain kinds of fanatical religious enthusiasm, but he also believed that the pinnacle of religious-moral-aesthetic experience consisted of an enthusiastic embrace of the spirit of the entire world.

The Cambridge Platonists

The Cambridge Platonists were a group of English seventeenth-century thinkers associated with the University of Cambridge. The most important philosophers among them were Henry More (1614-1687) and Ralph Cudworth (1617-1689), both fellows of Christ's College, Cambridge. The group also included Benjamin Whichcote (1609-1683), Peter Sterry (1613-1672), John Smith (1618-1652), Nathaniel Culverwell (1619-1651), John Worthington (1618-1671), all one-time fellows of Emmanuel College, Cambridge. Their younger followers included George Rust (d. 1670), Anne Conway (1630-1679) and John Norris (1657-1711). In so far as they all held the philosophy of Plato and Plotinus in high regard, the designation 'Platonist' is apt. However, they drew on a wide range of philosophical sources besides Platonism. Among ancient philosophers, they were well acquainted with Aristotle and with Stoicism. But they were also very much abreast of new developments in philosophy and science - with Descartes, Hobbes and Spinoza as well as Bacon, Boyle and the Royal Society. (Smith, Culverwell, Cudworth and More were among the first Englishmen to read Descartes). The framework within which they read and understood ancient and modern philosophy was that of the 'perennial philosophy' (*philosophia perenni*s) proposed originally by Italian Renaissance philosophers such as Marsilio Ficino, and Agostino Steucho, but also employed by Gottfried Wilhelm Leibniz. Not only did they share the Renaissance Humanist regard for the achievements of ancient philosophy, but like the Humanists of the Renaissance, their interest was dictated by their sense of the relevance of classical philosophy to contemporary life. They also emphatically repudiated the scholasticism that prevailed in academic philosophy and took a lively interest in the developments that brought about the scientific revolution. They therefore form part of the philosophical revolution of the seventeenth century, especially since they sought an alternative philosophical foundation to Aristotelianism which was waning fast in the face of challenges from scepticism and competing alternative philosophies, notably those of Hobbes and Descartes. They were the first philosophers to write primarily and consistently in the English language.

One difference between the Cambridge Platonists and their more famous philosophical contemporaries is that they all had a theological background. Nevertheless, convinced of the compatibility of reason and faith, they regarded philosophy as the legitimate concern of theologians and are distinguished by the high value they accorded human reason. They and devoted their considerable philosophical learning to religious and moral issues, to defending the existence of God and the immortality of the soul, and to formulating a practical ethics for Christian conduct. They held the eternal existence of moral principles and of truth and that the human mind is equipped with the principles of reason and morality. Their optimistic view of human nature is underscored by their emphasis on the freedom of the will. Their anti-determinism lead them to propose arguments for human autonomy. They were all dualists for whom mind is ontologically prior to matter, and for whom the truths of the mind are superior to sense-

knowledge. They were nevertheless moderns in natural philosophy who accepted post-Galilean science, and propounded an atomistic theory of matter. But they repudiated mechanistic natural philosophy in favour of the view that spirit is the fundamental causal principle in the operations of nature.

Benjamin Whichcote

Benjamin Whichcote is usually considered to be the founding father of Cambridge Platonism, by virtue of the fact that so many of them studied at Emmanuel College when he taught there. During the Civil War period, Whichcote was appointed Provost of King’s College, Cambridge, and he served as Vice Chancellor of the University in 1650. However, he was removed from his post at King’s College at the Restoration in 1660. and was obliged to seek employment elsewhere, as a clergyman in London. The interruption to his academic career may explain why he never published any philosophical treatises as such. The main source for his philosophical views are his posthumously-published sermons and aphorisms. Whichcote’s tolerant, optimistic and rational outlook set the intellectual tone for Cambridge Platonism. Whichcote’s philosophical views are grounded in his liberal theology. He held that God being supremely perfect is necessarily good, wise and loving. Whichcote regarded human nature as rational and perfectible, and he believed that it is through reason as much as revelation that God communicates with man. ‘God is the most knowable of any thing in the world’ (Patrides, 1969, p.58). Without reason we would have no means of demonstrating the existence of God, and no assurance that revelation is from God. By reason Whichcote did not mean the disputatious logic of the schools but discursive, demonstrative and practical reason enlightened by contemplation of the divine. He held that moral principles are immutable absolutes exist independently of human minds and institutions, and that virtuous conduct is grounded in reason. Whichcote’s *Aphorisms* amount to a manual of practical ethics which amply illustrates his conviction that the fruit reason is not ‘bare knowledge’ but action, or knowledge which ‘doth go forth into act’. It is through reason that we gain knowledge of the natural world, and recognise natural phenomena as ‘the EFFECTS OF GOD’. Although Whichcote’s published writings do not discuss natural philosophy as such, his recognition of the demonstrative value of natural philosophy for the argument from design anticipates the use of natural philosophy in the apologetics of Cudworth and More.

Culverwell, Smith and Sterry

Whichcote's optimism about human reason and his conviction that philosophy properly belonged within the domain of religion, is an outlook shared by the other Cambridge Platonists, all of whom affirmed the compatibility of reason and faith. The fullest statement of this position is Henry More's *The Apology of Henry More* (1664) which sets out rules for the application of reason in religious matters, stipulating the use of only those 'Philosophick theorems' which are 'solid and rational in themselves, nor really repugnant to the word of God'. Like Whichcote, Peter Sterry, John Smith and Nathaniel Culverwell are known only through posthumously published writings. The first published treatise by any of the Cambridge Platonists was Nathaniel Culverwell's *An Elegant and Learned Discourse of the Light of Nature* of 1652. Like the other Cambridge Platonists Culverwell emphasises the freedom of the will and proposes an innatist epistemology, according to which the mind is furnished with 'clear and indelible Principles' and reason an 'intellectual lamp' placed in the soul by God to enable it to understand God's will promulgated in the law of nature. These innate principles of the mind also moral principles. The soul is a divine spark, which derives knowledge by inward contemplation, not outward observation. Drawing on Suarez and Aquinas, as well as Platonist and contemporary philosophy, Culverwell was the only Cambridge Platonist to invoke natural law.

After studying at Emmanuel College, John Smith taught mathematics at Queen's College until his premature death in 1652. His *Select Discourses* (1659) discusses a number of metaphysical and epistemological issues relating to Chrstian belief - the existence of God, immortality of the soul and the rationality of religion. Smith outlines a hierarchy of four grades of cognitive ascent from sense combined with reason, through reason in conjunction with innate notions, and, thirdly, through disembodied, self-reflective reason; and finally divine love.

Peter Sterry too was educated at Emmanuel College, Cambridge. His *A Discourse of the Freedom of the Will* (1675) is the most visionary of all the writings of the Cambridge Platonists. But Sterry was more involved with events outside Cambridge than most of the others, on account of the fact that he was chaplain first to Lord Brooke and then to Oliver Cromwell. After the death of Cromwell he retired to a Christian community in East Sheen.. In his *Discourse* Sterry argues that freedom consists in acting in accordance with ones nature, appropriately to ones level of being, be it plant, animal or intellectual entity. Human liberty is grounded in the divine essence and entails liberty of the understanding and of the will.

Henry More

A life-long fellow of Christ's College, Cambridge, Henry More was the most prolific of the Cambridge Platonists. He was also the most directly engaged in contemporary philosophical debate: not only did he enter into correspondence with Descartes (between 1648 and 1649) but he also wrote against Hobbes, and was one of the earliest English critics of Spinoza (*Demonstrationem duarum* and *Epistola altera* both published in his *Opera omnia*, 1671). Although he eventually became a critic of Cartesianism he initially

advocated the teaching of Cartesianism in English Universities. More's published writings included, besides philosophy, poetry, theology and bible commentary. His main philosophical works are his *An Antidote Against Atheism* (1653), his *Of the Immortality of the Soul* (1659), *Enchiridion metaphysicum* (1671), and *Enchiridion ethicum* (1667). In these writings, More elaborated a philosophy of spirit which explained all the phenomena of mind and of the physical world as the activity of spiritual substance controlling inert matter. More conceived of both spirit and body as spatially extended, but defined spiritual substance as the obverse of material extension: where body is inert and solid, but divisible; spirit is active and penetrable, but indivisible. It was in his correspondence with Descartes that he first expounded his view that all substance, whether material or immaterial, is extended. As an example of non-material extension he proposed space, within which material extension is contained. He went on to argue space is infinite, anticipating that other native of Grantham, Isaac Newton. More also argued that God who is an infinite spirit is an extended being (*res extensa*). There are, therefore, conceptual parallels between the idea of God and the idea of space, a view which he elaborates in *Enchiridion metaphysicum*, where he argues that the properties of space are analogous to the attributes of God (infinity, immateriality, immobility etc.).

Within the category of spiritual substance More includes not just the souls of living creatures and God himself but the main intermediate causal agent of the cosmos, the Spirit of Nature (or 'Hylarchic Principle'). According to More the Spirit of Nature is the interface between the divine and the material. As a concept, it has affinities with Plato's *anima mundi* (world soul), and the Stoics' *pneuma*. The Spirit of Nature can also be understood as encapsulating 'certain general Modes and Lawes of Nature' (More, *A Collection*, Preface, p. xvi) since it is the Spirit of Nature that is responsible for uniting individual souls with bodies, and for ensuring the regular operation of non-animate nature. It is a 'Superintendant Cause' which combines efficient and telelological causality to ensure the smooth-running of the universe according to God's plan. More sought, by this hypothesis, to account for phenomena that apparently defy the laws of mechanical physics (for example the inter-vortical trajectory of comets, the sympathetic vibration of strings and tidal motion). More underpinned his soul-body dualism by his theory of 'vital congruity' which explains soul-body interaction as a sympathetic attraction between soul and body engineered by the operation the Spirit of Nature.

Like the other Cambridge Platonists, More was a religious apologist who used philosophy in defence of theism against the claims of rational atheists. The most important statement of More's theological position his *An Explanation of the Grand Mystery of Godliness* appeared in 1664, and propounds, in opposition to Calvinist pessimistic voluntarism, a moral, rational providentialism in which he vindicates the goodness and justice of God by invoking the Origenist doctrine of the pre-existence of the soul. The most consistent theme of his philosophical writings, are arguments for demonstrating the existence and providential nature of God. Indeed the foundation stone of More's apologetic enterprise is his philosophy of spirit, especially his arguments for the existence of incorporeal causal agents, that is, souls or spirits. Furthermore, More attempted to answer materialists like Thomas Hobbes whom he perceived as an atheist on account of his dismissal of the idea of incorporeal substance as non-sensical. More's strategy was to show that the same arguments that materialists use demonstrate the existence and properties of body, also support the obverse, the existence of incorporeal substances. In this way More sought to demonstrate that the *idea* of incorporeal substance, or spirit, was as intelligible as that of corporeal

substance, i.e. body. Like Plato (in *Laws* 10), More argues that the operations of the nature cannot be explained simply in terms of the chance collision of material particles. Rather we must posit some other source of activity, which More identifies as 'spirit'. It is a short step, he argues, from grasping the concept of spirit, to accepting the idea of an infinite spirit, namely God.

More underpins these *a priori* arguments for the existence of spirit, with a wide range of *a posteriori* arguments, taken from observed phenomena of nature to demonstrate the actions of spirit. Through this excursus into observational method he accumulated a wide variety of data ranging from experiments conducted by Robert Boyle and members of the Royal Society, to supernatural effects including cases of witchcraft and demons. He was censured by Boyle for misappropriating his experiments to endorse his hypothesis of the Spirit of Nature, and his apparent credulity, appears inconsistent with his otherwise rational philosophy, though it must be said that belief in witchcraft was not unusual in his time, and, secondly, was entirely consistent with the theory of spirit according to which to deny the existence of spirits good or evil, leads, logically to the denial of the existence of God. As he put it, alluding to James I's defence of episcopacy, 'That saying is no less true in Politicks " *No Bishop, no King*," than this in Metaphysicks, "*No Spirit, no God*" ' (More, 1662, *Antidote*, p. 142). His most well-known fellow-believer was Royal Society member, Joseph Glanvill (1636-1680), whose *Sadducismus triumphatus*, More edited.

More also published a short treatise on ethics entitled *Enchiridion Ethicum* (1667, translated as *An Account of Virtue*). Indebted to Descartes' theory of the passions this argues that knowledge of virtue is attainable by reason, and the pursuit of virtue entails the control of the passions by the soul. Motivation to good is supplied by rightly-directed emotion, while virtue is achieved by the exercise free will or *autoexousy* (More uses the same term as Cudworth), that is the 'Power to act or not act within ourselves'. Anticipating Shaftesbury's concept of moral sense More posits a special faculty of the soul combining reason and sensation which he calls the 'Boniform Faculty'.

More used a number of different genres for conveying his philosophical ideas. The most popular among these were his *Philosophical Poems* (1647) and his *Divine Dialogues* (1668). In *Conjectura cabbalistica* (1653), he presented core themes of his philosophy in the form of an exposition of occulted truths contained in the first book of Genesis. Subsequently he undertook a detailed study of the Jewish kabbalah which were published in Knorr von Rosenroth's *Kabbala denudata* (1679). These studies were based on the belief, then current, that kabbalistic writings contained, in symbolic form, original truths of philosophy, as well as of religion. Kabbalism therefore exemplified the compatibility of philosophy and faith. In addition to philosophy More published several studies of biblical prophecy (e.g. *Apocalypsis apocalypseos*, 1680, *Paralipomena prophetica*, 1685). In 1675, More prepared a Latin translation of his works, *Opera omnia* which ensured his philosophy reached a European audience as well as an English one.

Ralph Cudworth

Like his friend Henry More, Cudworth spent his entire career was as a teacher at the University of

Cambridge, where, in 1647, he was appointed Regius Professor of Hebrew and Master of Clare College. In 1654 he was elected Master of Christ's College, a post he held until his death. Cudworth published only one major work of philosophy in his lifetime, *The True Intellectual System of the Universe* (1678). Among the papers he left at his death, were the treatises published posthumously as *A Treatise Concerning Eternal and Immutable Morality* (1731) and his *A Treatise of Freewill* (1848). These papers also included two further manuscript treatises on the topic of 'Liberty and Necessity', which have never been published. Cudworth's humanistic erudition and baroque style have occluded the originality of his contribution to English philosophy and helped ensure to his undeserved neglect in the annals of English philosophy.

Cudworth's *True Intellectual System* propounds a an anti-determinist system of philosophy grounded in his conception of God as a fully perfect being, infinitely wise and good. The created world reflects the perfection, wisdom and goodness of its creator. It must, therefore be orderly, intelligible, and organised for the best. This anti-voluntarist understanding of God's attributes is also the foundation of epistemology and ethics, since God's wisdom and goodness are the guarantors of truth and of moral principles. By contrast, a philosophy founded on a voluntaristic conception of the deity would have no ground of certainty or of morality because it would depend on the arbitrary will of God who could, by arbitrary fiat, decree non-sense to be true and wrong to be right. It follows that misconceptions of God's attributes, which emphasise his power and will, result by definition in false philosopical systems with sceptical and atheistic implications.

Much of *The True Intellectual System* amounts to an extended *consensus gentium* argument for the existence of a supreme deity. By demonstrating from ancient sources that most ancient philosophers were theists, Cudworth sought to argue that theism is compatible with philosophy. Among the non-theists, Cudworth identifies four schools of atheistic philosophy, each of which is a type of materialism - Hylozoic atheism which attributes life to matter, Hylopathian atheism, which attributes all to matter, Cosmo-plastic atheism which makes the world-soul the highest numen. Each of these ancient brands of atheism has its latter-day manifestations in philosophers such as Hobbes (an example of a Hylopathian atheist) and Spinoza (a latter-day Hylozoist).

The true philosophy of Cudworth's intellectual system combines mechanistic atomism with Platonic metaphysics. Cudworth conceives this as having originated with Moses from whom it was transmitted via Pythagoras to Greek and other philosophers. Cudworth subscribed to the atomistic hypothesis that the created universe is constituted of particles of inert matter - indeed he regarded Cartesian mechanical philosophy as a recently revived variety of ancient atomism of Moses. But, for Cudworth, as for Plato, soul is ontologically prior to the physical world. Since motion, thought and action cannot be explained in terms of material particles, haphazardly jolted together, there must be some guiding originator, namely soul or spirit. Part of the appeal to Cudworth of the new 'mechanical' philosophy of Descartes was that, it was the dualism which underscored it. This Cudworth therefore interpreted Descartes' dualism with some latitude to explain all movement, life and action in terms of the activity of spirits operating on inert matter. Although he was critical of aspects of Cartesianism, he seized on its value for religious apologetics as instrumental in persuading materialists of the existence of spiritual agency.

In place of the mechanical explanation of the operations of nature, but proposed instead his hypothesis of 'the Plastick Life of Nature'. Similar in conception to More's Hylarchic Principle, Cudworth's Plastic Nature is a formative principle which acts as an intermediary between the divine and the natural world, maintaining the mundane operations of the physical universe. Plastic Nature, is the means whereby God imprints His presence on his creation and makes His wisdom and goodness manifest (and therefore intelligible) throughout created nature. In one respect, as Cudworth points out, Plastic Nature is a summation of all the laws of motion. At the same time he conceives it as having substance, as being some kind of spirit which carries out its functions unconsciously. Plastic Nature therefore has affinities with the Platonic *anima mundi*. The hypothesis of Plastic Nature also entails a teleological principle, which accounts for the design and purpose in the natural world. Plastic nature enables Cudworth to account for the providential ordering of the universe without falling into the trap of occasionalism. For by it he explains God's immanence in the world, without requiring immediate divine intervention in the minutiae of day-to-day operations in the natural world.

The Platonist principle that mind precedes the world lies at the foundation of Cudworth's epistemology which is discussed in *A Treatise of Eternal and Immutable Morality*. This is the most fully developed theory of knowledge by any of the Cambridge Platonists, and the most extensive treatment of innatism by any seventeenth-century philosopher. For Cudworth, as for Plato, ideas and moral principles 'are eternal and self-subsistent things'. The knowability of the world is explained in terms of the basic Platonic principles of archetype and ectype (form and copy). Cognition depends on the same principles, for just as the created world is a copy of the divine archetype, so also human minds contain the imprint of Divine wisdom and knowledge. The ideas in each individual mind are therefore the same in all minds. Since the human mind mirrors the mind of God, it is ready furnished with ideas and the ability to reason. Cognition therefore entails recollection and the ideas of things with which the mind thinks are therefore anticipations - Cudworth adopts the Stoic term *prolepsis* to denote them. But cognition is not a passive process. Rather it entails active participation of the mind. 'Knowledge', writes Cudworth, 'is not a passion from anything without the mind, but an active exertion of the inward strength, vigour, and power of the mind, displaying itself from within' (Cudworth, 1996, p. 74). Although innate knowledge is the only true knowledge, Cudworth's epistemology does not reject sense knowledge. On the contrary, sensory input is essential for knowledge of the body and the external world. And the external world is, intrinsically, intelligible, since it bears the imprint of its creator in the order and relationship of its component parts. However, raw sense data is not, by itself, knowledge. But it requires mental processing in order to become knowledge. As Cudworth puts it, we cannot understand the book of nature unless we know how to read.

Cudworth's theory of the mind as active is matched by an anti-determinist ethics of action, according to which the soul freely directs itself towards the good. In *A Treatise* Cudworth argues not only that ideas exist independently of human minds, but also the principles of morality are eternal and immutable. In a concerted attack on Hobbesian moral relativism, Cudworth, argues that the criteria of right and wrong, good and evil, justice and injustice are not a matter of convention, but are founded in the goodness and justice of God. Like Plato in the *Euthyphro*, Cudworth argues that it is not God's will that determines goodness, but that God wills things because they are good. The exercise of virtue is not, however, a passive process, but requires the free exercise of the individual will. Cudworth sets out his theory of free

will in three treatises on 'Liberty and Necessity', only one of which has been published, and that posthumously - *A Treatise of Freewill* (1848). According to Cudworth, the will is not a faculty of the soul, distinct from reason, but a power of the soul which combines the functions of both reason and will in order to direct the soul towards the good. Cudworth's use of the terms 'hegemonikon' (taken from Stoicism) and 'autexousion' (taken from Plotinus) underlines the fact that the exercise of will entails the power to act. It is internal direction, not external compulsion that induces us to act either morally or immorally. Without the freedom (and therefore power) to of act, there would be no moral responsibility. Moral conduct is active, not passive. Virtuous action is therefore a matter of active internal self-determination, rather than determination from without.

According to the moral psychology outlined in *A Treatise of Freewill*, the 'hegemonikon' has an integrative function within the soul, combining, on the one hand, the functions of will and reason, and, on the other the lower, animal, appetites of the soul with to the higher intellectual functions of the soul. In this way Cudworth bridges the divide between soul and body that characterises Cartesianism. Furthermore, Cudworth conceives of the *hegemonikon* not simply as the soul but the whole person, 'that which is properly we ourselves' (Cudworth, 1996, p. 178). Cudworth's concept of *hegemonikon* lays the basis for a concept of self identity founded in a subject that is at once thinking, autonomous and end-directed. Cudworth did not (as far as is known) develop a political philosophy. Nevertheless, the political implications of his ethical theory set him against Hobbes, but also, in many ways anticipate John Locke.

Legacy

After Hobbes and Locke, the Cambridge Platonists deserve to be considered an important third strand in English seventeenth-century philosophy. Their critique of Descartes, Hobbes, Spinoza has ensured that they are never ignored in philosophical history but they have yet to receive full recognition in their own right. Evidence from publication and citation suggests that their philosophical influence was more far-reaching than is normally recognised in modern histories of philosophy. The works of Cudworth and More were available to a European readership through Latin translation -More's *Opera omnia* appeared in 1675-9, and Cudworth's entire published works were translated into Latin by Johann Lorenz Mosheim and published in 1733. Among the immediate philosophical heirs of the Cambridge Platonists, mention should be made of Henry More's pupil, Anne Conway (1631-1679), one of the very few female philosophers of the period. Her *Principles of the Most Ancient and Modern Philosophy* (1692) entails a critique of More's dualistic philosophy of spirit, proposing instead a metaphysical monism that anticipates Leibniz. Another figure linked to More was John Norris (1657-1711) who was to become the leading English exponent of the philosophy of Malebranche. Whichcote's philosophical wisdom was admired by Anthony Ashley Cooper, third Earl of Shaftesbury who published his *Select Sermons* in 1698. Shaftesbury's tutor, John Locke was the intimate friend of Cudworth's philosophical daughter, Damaris Masham. The impact of Cudworth on Locke has yet to be fully investigated. Richard Price, and Thomas Reid were both indebted to Cudworth, whose theory of Plastic Nature was taken up in vitalist debates in the French enlightenment. Leibniz certainly read Cudworth and More. The intellectual legacy, the Cambridge Platonists extends not just to philosophical debate in seventeenth-century England but into European and Scottish Enlightenment thought and beyond.

Eighteenth Century German Philosophy Prior to Kant

In Germany, the eighteenth century was the age of enlightenment, the age, that is, that called for the independence of reason. Although the ethos of this age found its clearest (and certainly its most famous) articulation towards the end of the century with Immanuel Kant and his critical philosophy, he was not the first to issue this call. Instead, that task fell to Christian Thomasius (Thomas) at the end of the seventeenth century. It was then taken up and further developed in a theological (pietist) direction by a number of minor figures, the Thomasians, and reissued in a rationalist direction in the early and middle part of the eighteenth century by Christian Wolff and his followers. The development of their position(s) as well as their philosophical (dis)agreements took place by and large at the University of Halle and against the context of pietism.

Christian Thomasius (1655-1724)

Although Thomasius is now largely forgotten, he was a pivotal figure in early eighteenth century enlightenment thought. In this context, however, he was also a somewhat ambiguous figure. On the one hand, he was clearly an innovator. Both a lawyer and a philosophy professor, he advocated the independent use of healthy reason, fought against prejudice, against belief in any of the then prevailing superstitions, against any form of (religious) persecution, against the witch-hunt and the use of torture, and in general, against any form of intolerance. He took issue with dependence on authority and the school philosophy's dependence on the syllogism. He lectured in German rather than the traditional Latin or the then fashionable French and was the first person, in Germany, to found a popular monthly journal, written by and large in German, devoted to book reviews, the *Monatsgespräche* (*Monthly Conversations*). On the other hand, especially when it came to matters of morality, he was more of a traditionalist. Here he retained distinctly non-Enlightenment ideas, particularly the belief in an evil will and the belief in the necessity of God's salvation.

Biography/Work

By way of background to both Thomasius's and Wolff's life it is important to note that the Germany of the eighteenth century was a country split into numerous states, each of which had its own government. There was no central government. Reeling from the effects of the Thirty Years War, many of its states did not have freedom of speech, freedom of religion, or, for that matter, a ‘national’ culture, though, given the variety of state governments, some states had relatively more freedom than others. It may seem surprising, therefore, that Christian Thomasius was able to issue the call to the enlightenment at the end of the seventeenth century, though not at all surprising that both Thomasius and Wolff were subject to arbitrary political power.

The son of jurist and philosopher Jakob Thomasius, Christian received his education at the University of Leipzig and his law degree at the University of Frankfurt an der Oder (in Eastern Germany) in 1679. He spent the early part of his career in his hometown Leipzig (in the state of Saxony), as a lawyer and (private) lecturer at the university there, but his controversial views and manner of expressing them, in particular, in the monthly journal *Monatsgespräche*, led to the prohibition to publish and hold lectures (private and academic) in Leipzig (and Saxony) in 1690. He was, however, welcome in the neighboring and comparatively more open-minded Halle (in the state of Brandenburg/Prussia), and was instrumental in founding the university there in 1694. He remained in Halle for the rest of his life, refusing an invitation to return to Leipzig in 1709.

Thomasius's body of work can be roughly divided into three parts. In his early Leipzig years, he was primarily interested in matters of law, particularly, following his father, in Pufendorf's natural law theory. This period ends around 1688 with the publication of *Institutiones jurisprudentiae divinae* (*Institutions of Divine Jurisprudence*) in which he sought to complete Pufendorf's project of divorcing natural law from theology. This year, as well, saw the publication of *Introductio ad philosophiam auliam* (*Introduction to Court Philosophy*), a text that is somewhat misnamed since it has less to do with proper conduct or even thought at court than with the proper use of reason, a topic that Thomasius would take up in greater detail in his 1691 *Introduction to the Doctrine of Reason*.

In general, 1687-8 seems to have marked an endpoint of sorts and the beginning of the second major stage, the more clearly philosophical one, of Thomasius's life. Even though he would remain in Leipzig for another two years, he had clearly broken with tradition by 1687, when he began lecturing and publishing in German. In 1688, he began the publication of the controversial *Monatsgespräche* (which appeared monthly until April 1690) and turned his attention to matters of theoretical and practical philosophy. Here two sets of books, the *Einleitung* and *Ausübung der Vernunftlehre* (*Introduction* and *Application of the Doctrine of Reason*), and the *Einleitung* and *Ausübung der Sittenlehre (Introduction* and *Application of Moral Theory*) that appeared in Halle between 1691 and 1696 mark the second part of his career. Written by and large in German with a minimum of technical terminology, these books were intended not for an audience of experts, but instead, as the subtitle to the *Introduction to the Doctrine of Reason* specifies, for a general audience of “all rational persons of whatever social standing and sex…”

During the late 1690s (and after a religious crisis that led to an at least temporary (re)affirmation of his pietist beliefs), Thomasius produced two works on metaphysics that endorsed a mystical variety of vitalism. In subsequent years, his interests shifted back to matters of law. This was the third part of his life and will not be further considered in this context.

Philosophy

Thomasius's philosophical stance was an empiricist one, not the rationalism that we find in much of the philosophical tradition and with Wolff. It is true that his belief in natural human reason and its capacity to find truth suggests a mild rationalism, but Thomasius abhorred innate ideas and maintained that all knowledge, all thought, begins with sense perception. This strong sensationism (which has similarities with Locke's position) was coupled, as has already been noted, with an enlightenment stance, in the sense that it was governed by the conviction that knowledge, truth and morality are the purview of everyone, not merely the elect few. The latter is particularly evident in the differentiation between *Gelehrtheit* and *Gelahrtheit* that he drew at the outset of the *Introduction to the Doctrine of Reason*. *Gelehrtheit* or academic learning is the domain of experts who are familiar with syllogistic logic, metaphysics, epistemology, and theology, but *Gelahrtheit* or practical learning is available to everyone with a healthy reason who pursues knowledge not for its own sake but for the use-value it has in daily life.

Thomasius's enlightenment convictions are similarly evident in his eclecticism. Though generally deemed a negative stance, this is not the case for Thomasius. He considers it positively as a corrective to any form of sectarian dogmatism. By his own account, he was influenced by several of his predecessors, notably, in Germany, Grotius and Pufendorf and, in England, Hobbes and Locke, and he appropriated those aspects of their theories that he found conducive to his overall aim: the spread of the Enlightenment ethos, understood here as the project of ensuring a healthy reason, one that can discover truth, that can lay open contradictions and fight prejudices.

Given Thomasius's basic presuppositions of where knowledge is likely to be found (in daily life rather than abstract speculation) and who is most likely to attain it (the person who has a healthy reason, not one

corrupted by prejudices), it is likely not surprising that his epistemology was not a theoretical one. His two books on theoretical philosophy, the *Introduction to the Doctrine of Reason* and the *Application of the Doctrine of Reason*, are books on truth. They are not, however, books on truth in the traditional sense. Thomasius did not develop a philosophical conception of truth or of the condition of its possibility. He seems to have simply adopted a correspondence theory of truth and to have taken the harmony of thought and thing as a given. Certainly, this harmony was not the problem for him that it was for 17th century thought and that it would be again in the later part of the 18th century (with Wolff, Knutsen and Kant). What mattered to Thomasius is the enlightenment optimism that truth is possible and, moreover, accessible to everyone. His *Introduction*, accordingly, was presented, as specified by the book's subtitle, as providing the means by which "all rational persons, of whatever social standing and sex, are shown in an understandable manner, and without the aid of syllogisms, how to differentiate between the true, the probable and the false, and to find new truths." It is a book of instruction in proper or correct use of healthy reason.

His *Application* continued this theme, though this time by providing people with the means of avoiding error. Avoiding error involves the eradication of prejudices, which are among the causes of the corruption of reason. That, in turn, is accomplished through what he identifies as dogmatic doubt, not the Cartesian doubt that deems everything false so as to find a first indubitable principle, a useless enterprise, according to Thomasius. Dogmatic doubt is the doubt about particular things, beliefs, and opinions, and this he found healthy and conducive to preventing error.

Thomasius's enlightenment convictions are not, however, as straightforward as might appear. He did believe in natural reason's capacity to overcome corruption, but even as he adhered to this view, he held that an evil will is at the root of this corruption, and that we require God's grace. This conflict is particularly evident in his moral philosophy. While his initial presentation was an optimistic affirmation of the viability of a moral position he identified as one involving "rational love" (*vernünftige Liebe*) as the only means to a "happy, courteous and cheerful life," as indicated by the subtitle of the *Introduction to Moral Theory*, by 1696, he had become disenchanted with this view. Human self-interest and an evil will stand in its way.

Thomasius's moral theory is a theory of the will. He held that in moral matters, the will dominates reason. Though human beings have free choice if not externally constrained, the will is not free. Rather, it is dominated by human affects; our passions, impulses, and desires. Like Hobbes, Thomasius believed that even though subject to such inner (psychological) constraints, the will still chooses (with the aid of reason); it consciously wills. And a conscious choice is precisely what is required for a (good) action to be considered moral, a good instinct or good inclinations may make us good, may even be desirable, but by itself this is not enough to make us moral. Morality requires a conscious act of will. The trouble with morality arises because the will is determined by evil desires, in particular, lust, ambition, and avarice. Although there are noble sentiments as well, which similarly influence the will, they are in conflict with the negative dispositions. The conflict can be brought to a positive conclusion only by appeal to divine grace (God's salvation).

This ambivalence and return to theology aside, Thomasius's moral position is an interesting one. The

theory of rational love is based on the fundamental equality of human beings as well as on their ability to think and choose independently (of authority). Ultimately, Thomasius's ethics is a social ethics. The theory is other-directed, and given the absence of laws and principles, constitutes a nice contrast to the formalist universalist ethics Kant would develop by the end of the next century. At the same time, the lack of any way of making this theory applicable in a context governed not by similar but instead by conflicting interests, makes something like a fomalist ethics an inevitability. By the end of the *Introduction to Moral Theory*, even Thomasius recognises that “rational love” will function only in relatively harmonious contexts, in others, particularly those characterised by unequal power positions, justice may well be required.

Christian Wolff (1679-1754)

It is without question that Christian Wolff was the most important German philosopher in the early and middle portion of the eighteenth century. Dissatisfied with the, to his mind, arbitrary eclecticism advocated by Thomasius and his ‘school,’ and equally dissatisfied with the scholastic school metaphysics which, he thought, lacked rigour, he produced a systematic philosophical system in reply. Indeed, his philosophy is reputed to constitute the most coherent systematic whole produced in the 18th century prior to Kant. As an enlightenment thinker, albeit a rationalist one, he was, like Thomasius, committed to public education. He saw philosophy, which he conceived as world-wisdom (*Welt-Weisheit*), as the means to public enlightenment and, in line with the mood of the time, the purview of everyone, not just of philosophers or experts. To make it accessible, he wrote in German, at least during his Halle years, and introduced much of the German philosophical terminology that is still used (the concepts of *Bewußtsein*, *Vorstellung*, and *Begriff* have their origin here).

Biography/Work

Wolff's birthplace was Breslau (then in Eastern Germany, now in Poland). At an early age, dissatisfied with orthodox theology, he turned to the study of mathematics as offering the best means to certainty. He studied theology and mathematics at the University of Jena and gained his Master's degree in Leizpig in 1702. Influenced by von Tschirnhaus and while working in Leipzig as a private lecturer, he wrote a dissertation seeking to apply the mathematical method to problems in practical philosophy. This drew Leibniz's attention to him. They began a correspondence that continued until Leibniz's death in 1716. Sponsored by Leibniz and von Tschirnhaus, he was appointed Professor of Mathematics and Natural Science at the University of Halle in 1707.

Since his position in Halle was predominantly as a teacher of mathematics -- a task at which he excelled -- Wolff did not begin lecturing and writing on philosophical matters until 1710. In mathematics, he produced textbooks, a four volume history of mathematics in 1710 and a mathematical dictionary in 1711. His philosophical lectures were in the first instance expositions of Leibniz's philosophy, which led his opponents (the representatives of the Thomasius ‘school’) to identify his philosophy as the Leibniz-Wolffian philosophy, a designation that remained despite his objection. He began an extensive series of publications, in German and often identified as his German works, on philosophical topics -- the “German

Logic” in 1713, the “German Metaphysics” in 1719, the “German Ethics” in 1720, the “German Politics” in 1721, the “German Cosmology” in 1723, and the “German Theology” in 1724, along with numerous short essays. Given his success as a teacher and fame as an author, he gained increasing prominence in Halle, much to the dismay of the “Thomasians” who had dominated philosophical instruction there. It did not contribute to a smooth collegial relationship that Wolff did not like Thomasius's eclectic philosophy and did not hide his dislike. Matters came to a head in 1721 when some political maneuvering on the part of his opponents (the “Thomasians” and the pietists) likely prompted by his own increasing fame and popularity with the students combined with his apparently difficult personality, brought him to the attention of the emperor in Berlin, Friedrich Wilhelm I, who expelled him from Prussia in 1723 on threat of hanging.

Having earlier been invited to the University of Marburg, he took up the position there. At the time Marburg was a more cosmopolitan place than Halle, and Wolff now had students from other countries. He saw himself as speaking to Europeans, not merely Germans, and began writing in Latin. In fact, he produced a second series of books, in Latin and identified as his Latin works, going over the same subject matter that he had treated in his German texts, albeit in more detail. Though even more scholastic than the earlier German texts, these books contributed to his fame in a much broader context (Europe rather than Germany). In 1733, Friedrich Wilhelm I invited him to return to Prussia, but Wolff declined this invitation. He became increasingly well established, so much so that a cabinet order of 1739 required candidates for the ministry to study Wolff's books, particularly his logic. In short order, Wolffians and Wolff societies could be found everywhere, even in Prussia. In 1740, Frederick the Great recalled him to Prussia, offering a permanent fellowship in the Berlin Academy. Rather than accept the invitation to Berlin, he returned to Halle to great acclaim and public approbation. To his disappointment, however, the mood in Halle had changed, the residing Wolffians, in particular Baumgarten, had begun to develop his thought, and his lectures were not successful. Complaining about the poor quality of the students, he gave up lecturing but continued writing.

Philosophy

Wolff was not an original philosopher, but a modernizer and systematiser. Rather than reject scholastic school philosophy outright, as Thomasius had done, he modernized and systematised it (and philosophy as a whole). Systematizing philosophy meant integrating different ideas from the philosophical tradition -- Descartes's concept of substance, for instance, and Leibniz's theory of pre-established harmony. But while eclectic in this sense, unlike Thomasius's thought, Wolff's was anything but arbitrary. Rather, he combined those ingredients into a comprehensive system on the model of mathematics. Mathematics was, for Wolff, a systematic science operating by definition and syllogistic proof, and this was the method he strove to make applicable to philosophy. In philosophy, the method was cashed out in a combined analytic/synthetic manner. Definitions were arrived at analytically -- the analysis was to be of empirical matters and was to convey simple ideas through a process of clarification, abstraction, and analysis. These were then combined into definitions. The definitions were to function as ingredients in the syllogisms that returned, synthetically, to the empirical starting point, though it is presumably now understood why things are as they are, an understanding that was, for Wolff, the goal of philosophy.

The first philosophy text Wolff produced was his “German Logic” (*Vernünfftige Gedancken von den Kräften des menschlichen Verstandes und ihrem richtigen Gebrauche in Erkenntnis der Wahrheit*). Logic is of central importance to Wolff because it sets out the rules for thought, which is understanding's ability to forge connections, according to Wolff a uniquely human ability. All human beings have natural understanding, but by itself this is not sufficient. Logic or the “art of demonstration” serves to refine this natural capacity and functions, as well, as the condition of science. From the point of view of the enlightenment, it is instructive here that Wolff insisted, as Thomasius had before him, that book and memory learning is not the same as knowledge. That requires the use of the powers of the understanding, and above all, much practice in the art of thought. While innate, the powers of understanding have to be honed through practice/experience.

Wolff's second philosophical treatise, the “German Metaphysics” (*Vernünfftige Gedancken von Gott, der Welt und der Seele des Menschen, auch allen Dingen überhaupt*) appeared some seven years after the “German Logic”. Just as that had vindicated the discipline of logic against the early enlightenment attacks, so this vindicated the discipline of metaphysics, understood as the “science of the possible as possible.” After a brief introductory chapter identifying his Cartesian stance by linking existence to consciousness (we must exist because we are conscious of ourselves), the “German Metaphysics” treats ontology, empirical psychology, cosmology, rational psychology and natural theology. In the second chapter Wolff sets out the two (Leibnizian) principles governing his philosophical thought: the principle of contradiction (“something cannot both be and not be at the same time” §10, 6) and the principle of sufficient reason (“everything that is must have a sufficient reason why it is” §30, 17). These are significant not only from the point of view of Wolff's thought but also in light of the role they would play in early Kant-criticism. In the chapter on rational psychology (chapter 5), he defends the Leibnizian conception of pre-established harmony (§765, 478-9) and, in the final chapter on natural theology, he tells his readers that the world mirrors God's perfection (§1045, 648). These are aspects of Wolff's position with which the (pietist) Thomasians would take issue.

After the “German Metaphysics” appeared, Wolff published about a book a year dealing with and integrating into his system other central philosophical matters: ethics in 1720, politics in 1721, physics in 1723, teleology in 1724 and biology in 1724.

The ethics (*Vernünfftige Gedancken von der Menschen Thun und Lassen, zu Berförderung ihrer Glückseligkeit*) is composed of four parts, a theoretical part that treats the foundation of practical philosophy and three practical parts that present a doctrine of duties that human beings have to themselves, to God, and to others. Not surprisingly, given that Wolff believes the world to mirror God's perfection, the issue in the ethics is perfection as well and not, as with Thomasius, happiness (that is left for his politics). Moral perfection is the guideline by which we ought to choose between two (or more) equally possible actions. That is to say, when making a free choice we ought to consider whether the action “promotes the perfection of our inner and outer state” (§2, 5) and that means considering whether the state of the soul and the body accords with the prior state or contradicts it. The outcome has greater perfection to the extent that it contributes to the continued “natural human state and its harmonious preservation over time”(§2, 5). The natural human state Wolff envisions is the state of the soul in its manifold efforts to find truth, and everything has to be done to maximize that state (see “German

Metaphysics” §152, 79). It so happens, that this is where happiness lies as well, and as Wolff indicates at the end of the ethics, it is incumbent upon human beings to ensure not only their own perfection/happiness, but to “contribute as much as possible to the happiness of others” (§767, 539).

In the “German Politics” (*Vernünfftige Gedancken von dem gesellschaftlichen Leben der Menschen und insonderheit dem gemeinen Wesen*), he proceeds to investigate the varieties of human societies and to specify how they ought to be set up so as to “promote the uninhibited progression to the common best” (§3, 3). A society must accord with the laws of nature, otherwise it cannot be considered a society, and accord with the laws of nature surely means perfection/happiness.

Wolff's Latin works appeared with equal regularity in the 1730, with the “Latin Logic” (*Philosophia rationalis sive logica*) beginning the series in 1728. In spite of their greater thoroughness, or perhaps because of it, they were not as widely read either in Germany or Europe as a whole. Whereas the German texts went through several reprints (14 for the Logic, 10 for the Metaphysics), the “Latin Logic” was only reprinted three times, and some of the other Latin texts perhaps twice. By the 1730s the German texts had established Wolff's influence and the Latin texts did little to change that. They will, accordingly, not be further considered in this context.

Context, Influences and Disciples

Both Thomasius and Wolff had followers. In Thomasius's case this was in spite of the fact that he claimed to have no desire to have disciples or found a school. But given the influence he had on his contemporaries, it would have been surprising if there had not been anyone who saw himself as following in his footsteps and, more importantly, taking up his cause (against Wolff). Among Thomasius's contemporaries to do so were Franz Budde (1667-1729), Joachim Lange (1670-1744), Andreas Rüdiger (1673-1731), and Adolf Friedrich Hoffmann (1707-1741). Christian August Crusius (?1715-1775) was a later follower (Hoffmann's student) who came on the philosophical scene when Wolffianism was already starting to decline.

Wolff's followers were perhaps more varied than those following and rejecting Thomasius. Indeed, by the 1740s, Wolffianism had become the leading German philosophy and had spread to the major German universities: to Halle (with Wolff, A. G. Baumgarten, though he moved on to Frankfurt an der Oder), G. F. Meier, and J. A. Eberhard, who is known particularly for the role he played in early Kant-criticism), to Marburg where virtually every academic was a Wolffian, to Giessen (with J. F. Müller, and Böhm), to Tübingen (with Georg Bernhard Bilfinger, Israel Gottlob Ganz and Gottfried Plouquet), to Leipzig (with Gottsched and Ludovici), to Jena (with Johann Peter Reusch and Joachim George Darjes), and to Königsberg (with Knutsen, Kant's teacher).

The reception of Wolff's philosophy is interesting not only in view of its widespread acceptance, but also in light of the disputes it generated and the further developments it gave rise to. Chief among these disputes were (1) the attack by the pietists (Budde and Lange) that led to Wolff's dismissal from Halle and (2) the attack by the Thomasians (Hoffmann and Crusius). Further developments of the Wolffian

philosophy can be found particularly in the domain of aesthetics with Gottsched and Baumgarten.

Pietism

The development of early and even mid-enlightenment thought in 18th century Germany proceeded hand in hand with the then relatively new (protestant) religious trend: pietism. Like the discontent that the representatives of the early enlightenment had with authority and, at least in the early years, intellectual life, those of pietism took issue with the (religious) orthodoxy and its intellectualism. Furthermore, rather than endorse obedience and conformity to the establishment, the pietist movement emphasized the subjective aspect of faith: a person's experience, feeling, and, above all, personal participation in religious matters and performances. The emphasis on the subjective and personal, and on people's actual participation in religion made pietism an ideal companion for early enlightenment thought. At issue here was not academic competence, not the cognitive aspect of religion, but its affective aspect with emphasis on devotion and practical service, just as what was at issue in the early enlightenment was not the intellectual aspect of reason, but its practical performance and service. And both movements were characterized by a commitment to egalitarianism.

This is not to say that the parallel development was always or even necessarily harmonious. In Halle, the chief representative of pietism was August Hermann Francke (1663-1722), who had been brought there by Thomasius. But Thomasius and Francke did not see eye to eye on all matters. While Thomasius had endorsed Francke's practical activism (he was the founder of the Halle orphanage), he broke with Francke by 1699, criticising his educational policies for producing “uneducated, melancholy, fantastic, obstinate, recalcitrant, and spiteful men” (cited in Beck, 253). It is not clear what, if any, philosophical reasons Thomasius had for turning against Francke. However, the details of their disagreement are not important for the development of 18th century philosophy.

the Thomasians

Budde and Lange, both ultimately Professors of Theology at Jena and Halle respectively, developed Thomasius's thought in a theological (pietist) direction. That is to say, both, and Lange more so than Budde, emphasized the need for revelation to a greater extent that Thomasius had done, as they also claimed that the source of evil was the will and that the root cause of evil was original sin. Though Thomasius could be found to hold these views as well, particularly during the completion of his *Application of Moral Theory*, their difference from Thomasius lies in the emphasis they placed on these views. Moreover, in his major work, *Medicina Mentis,* Lange devoted a great deal of attention to demonstrating how the ill or corrupt will and mind might be healed.

It is interesting that there were differences not just from the theological dimension of Thomasius's thought, but also in the philosophical respect. Here it is particularly noteworthy that in his philosophical texts Budde sought a systematic whole and was not content to adopt Thomasius's more eclectic style. Though he claimed to be an eclectic, he thought this did not entail that he could not provide a unified whole. That whole is provided by his three books in philosophy. The theoretical philosophy can be found

in the *Institutiones Philosophiae Eclecticae* that appeared in two parts in Halle in 1703. The two parts are the “Elementa philosophiae theoreticae,” roughly a metaphysics, and the “Elementa philosophiae instrumentalis,” Budde's logic. Along with the earlier work in practical philosophy, the *Elementae Philosophiae Practicae*, originally published in 1697 but significantly revised for the 1703 edition, these texts constitute Budde's philosophical system.

Rüdiger, Hoffmann, and Crusius were related through teacher-student relationships with Rüdiger teaching Hoffmann who then taught Crusius. See below (Disputes) for an account of the role they, and Crusius in particular, played in the disagreement of the Thomasians with Wolff.

the Wolffians

Wolff's enlightenment rationalism had made a decisive impact on the philosophical scene in Germany in the 1720s. Over the middle years of the 18thcentury, and against objections from both Thomasians and pietism, Wolffianism took hold, at least for a time. Certainly, the events that led to his expulsion from Halle contributed to his notoriety and fame. Philosophers took up his cause in virtually all the universities in Eastern and Northern Germany, occasionally developing his philosophical system in different directions. Among the chief representatives of Wolffianism were, in Leipzig, J. C. Gottsched (1700-1766), in Frankfurt am Main, Alexander Gottlieb Baumgarten (1714-62) and H. F. Meier, who were instrumental in founding Aesthetics, in Königsberg, Kant's teacher Martin Knutsen (1713-51). Wolffianism also played a central role in the early criticisms of Kant's critical philosophy. There it was represented primarily by Eberhard, Maaß, and Schwab and in the major review journal at the time, Nicolai's *Allgemeine deutsche Bibliothek*. (See Allison, *The Kant-Eberhard Controversy*). There can be no question that Wolffianism dominated German universities during the 1720s to the 1740s, though it disintegrated to some extent soon after his death in 1754 with, among other things, the development of aesthetics.

Disputes

Given the two radically different approaches to issuing the enlightenment call to the independent use of reason that we find in the 18th century, it is not surprising that the age should have its share of disputes. This was particularly evident in the disagreements surrounding Wolff and Wolffianism. It has already been indicated above that two attacks in particular stand out (1) the attack that led to his expulsion from Halle and (2) the attack that was mounted by Hoffmann and Crusius.

The first attack was mounted by Thomasius's pietist followers. They, in particular Budde and Lange, centered their opposition to Wolffianism around the fatalism and Spinozism they thought implied by his system. Also, Wolff's dependence on the mathematical method and the subordination of the divine will to necessity were questioned. Similarly, the Leibnizian doctrine of pre-established harmony of soul and body that the critics attributed to Wolff was thought to be at odds with the possibility of free will, and with that, responsibility for our actions. If the interaction of soul and body has to be pre-ordained or pre-established, then it is not possible that we could act otherwise than we have been determined to act, and

the notions of responsibility and sin are only a chimera. It must be added here that the critique of the belief in a free will is justified. Wolff struggled with this possibility as much as Leibniz had done, and it is simply not clear that given their adherence to pre-established harmony, either one managed to resolve the conundrum on the ontological level.

It is an interesting footnote to these disputes that while Thomasius himself did not participate in these disputes, Wolff did. In 1724 he published a detailed reply to Budde and Lange's critique of the German Metaphysics (*Kleine Kontroversschriften mit Joachim Lange und Johann Franz Budde*) and he also took their concerns up in the *Anmerkungen* to the German Metaphysics.

The second attack was mounted by those Thomasians who did not foreground their pietism, Andreas Rüdiger (1673-1731), Adolf Friedrich Hoffmann (1707-1741), and Christian August Crusius (?1715-1775). Rüdiger and Hoffmann attacked Wolff on a number of issues (the relation of mind and body, for instance, which they took to constitute a unity, not two distinct substances, the difference between the mathematical and the philosophical methods, and the question of the will's role in ethics). At least some of these issues were taken up by Crusius, who was the last Thomasian to take issue with Wolff.

Crusius did his philosophical work in Leipzig in the 1740s before taking on the professorship of Theology in 1751. Like earlier Thomasians, he questioned Wolff's subordination of the will to reason, arguing for the freedom of the former against what he takes to be Wolff's fatalism, though he was willing to concede that the will requires understanding. Perhaps the most significant aspect of Crusius' thought was his differentiation between the philosophical and mathematical methods. Whereas mathematics is said to be grounded on the principle of contradiction, this is not the case for philosophy. That has to do with real objects, with nature, its structures and forces, not with the abstract and artificial concepts of mathematics. At the same time, he also thought there was a role for mathematics in the analysis of nature -- it could provide concepts of bodies and their relations. Of course, as his contemporaries pointed out, one wonders why mathematics should have a role in the investigation of the “real” world if the nature of its abstraction made it distinct from the (concrete) real world. Crusius did not have an answer to these questions, but it was a topic that Kant would take on in his pre-critical project.

Beyond Wolff

With the decline of Wolffianism after 1754, German philosophy was for a time at loose ends. The decline was prompted not only by the criticisms offered by the Thomasians, but also by the internal developments of Wolffianism proposed by various of Wolff's disciples. Hermann Samuel Reimarus (1694-1768), for instance, developed a rationalist critique of revelation, arguing that for the rational person religion had to be based on reason (*Apologie oder Schützschrift für die vernünftigen Verehrer Gottes*, published posthumously). Others began to extend Wolffianism into areas Wolff himself had not considered, thereby contributing to significant development. Here the area of aesthetics is paramount. Moreover, by the middle of the 18th century, French and English (particularly) Scottish philosophy (Hume's *Inquiry*, Locke's *Essay* along with other texts by Hume, Reid, Hutcheson, Beattie, Condillac) began to be available in translation, thus offering a clear (empiricist) alternative to Wolffian rationalism. These texts were

immensely influential. Recall Kant's claim that his recollection of David Hume had awoken him from his dogmatic slumber (*Prolegomena*, *Ak*. IV, 260). The empiricists, for instance Feder and Garve also played a significant role in early Kant-criticism (see Sassen, *Kant's Early Critics*). By and large, the period of 18th century German philosophy after 1750 and before 1781 was a period not of any one dominant school, but of individuals loosely associated with a number of different trends. Among individuals who cannot be clearly assigned anywhere were Johann Heinrich Lambert, Moses Mendelssohn and Johann Nikolaus Tetens. Not either Thomasians or Wolffians, they must be considered in relation to Kant's pre-critical and critical philosophy, not from the point of view of German philosophy prior to Kant.

Aesthetics

Even though Wolff sought to integrate virtually all aspects of philosophy into his system, he had nothing to say about the philosophy of art. In some way this is not surprising if we consider that in the Germany of the early Enlightenment, the arts, particularly poetry and literature, were as good as nonexistent. The German literary greats had not even been born when Wolff wrote his German texts (Lessing was born in 1729, Herder in 1744, Goethe in 1749). First to develop a theory of the arts, particularly poetry, was Johann Christoph Gottsched (1700-1766), who published his ‘Critical Poetry’ (*Versuch einer critischen Dichtkunst vor die Deutschen*) in 1730. Treating poetry scientifically, he set out a set of rules that were to guide the composition. Given his conception of what a poem was (a moral fable) and given as well his idea of what was involved in its composition (a set of rules), there was little room here for beauty and even less for sentiment and inspiration. But sentiment and inspiration was precisely the direction in which poetry was going by the middle of the century. Gottsched's Wolffian philosophy of poetry, accordingly, was quickly supplanted by Johann Jakob Breitinger's *Critische Abhandlung* (1740), a book that emphasized the *a posteriori* experience of poetry, not its rule-bound composition.

A quasi-Wolffian synthesis of these two approaches was brought about by Alexander Gottlieb Baumgarten (1714-1762), probably Wolff's most famous disciple. Baumgarten produced two major texts, his metaphysics in 1739 (*Metaphysica*), which Kant would use as a textbook, and, in 1750 and 1758, his aesthetics *(Aesthetica*). That he designated the term ‘aesthetics’ to identify the philosophy of art, particularly poetry, would hardly be thought important had he done nothing else. However, in developing the ‘field’ of aesthetics, he also contributed significantly to the study of the senses. Whereas Wolff had conceived of the senses merely as providing the raw material for processing, a task performed by understanding and governed by the rules of logic, Baumgarten thought that the senses had their own rules and their own perfection, rules and perfection that differ from logical rules and the knowledge generated by logical processing. The rules of sensation are studied by the science of perception, which Baumgarten called aesthetics. But aesthetics is also the study of poetry. In *Reflections on Poetry* he set out the notion of aesthetic clarity. Although poetic representations are confused representations (§14, 42), they have sensuous clarity. Baumgarten identified this clarity as *extensive* clarity to differentiate it from the *intensive* clarity of logic (§17, 43). Appealing to the senses, poetic representation can be more illuminating than representations produced by logical processing and reasoning. Moreover, appealing to the affects, such representations are connected to pleasure. One cannot but see the influence that Baumgarten likely had on Kant's critical philosophy -- his vindication of the senses reappears in an inherently Kantian way both in the Transcendental Aesthetic of the *Critique of Pure Reason* and in the

Critique of Judgment.

Justice as a Virtue

When we speak of justice as a virtue, we are usually referring to a trait of individuals, even if we conceive the justice of individuals as having some (grounding) reference to social justice. But Rawls and others regard justice as "the first virtue of social institutions" (1971, p. 3), so "justice as a virtue" is actually ambiguous as between individual and social applications. This essay will reflect and explore that ambiguity, though the principal focus will understandably be on the justice of individuals.

However, even the idea of individual justice seems ambiguous in regard to scope. Plato in the Republic treats justice as an overarching virtue of individuals (and of societies), meaning that almost every issue he (or we) would regard as ethical comes in under the notion of justice (dikaosoune). But in modern usages justice covers only part of individual morality, and we don't readily think of someone as unjust if they lie or neglect their children--other epithets more readily spring to mind. What individual justice most naturally refers to are moral issues having to do with goods or property. It is, we say, unjust for someone to steal from people or not to give them what he owes them, and it is also unjust if someone called upon to distribute something good (or bad or both) among members of a group uses an arbitrary or unjustified basis for making the distribution (this last aspect of individual justice obviously has reference to social or at least group justice). Discussion of justice as an individual virtue standardly (at least) centers on questions, therefore, about property and other distributable goods.

1. History

Although the idea of social justice based in a social contract is mentioned in Plato's Republic and was

known even earlier, the Republic's conception of individual justice is distinctively virtue ethical. To be sure, Plato understands individual justice on analogy with justice "writ large" in the state, but he views the state, or republic, as a kind of organism or beehive, and the justice of individuals is not thought of as primarily involving conformity to just institutions and laws. Rather, the just individual is someone whose soul is guided by a vision of the Good, someone in whom reason governs passion and ambition through such a vision. When, but only when, this is the case, is the soul harmonious, strong, beautiful, and healthy, and individual justice precisely consists in such a state of the soul. Actions are then just if the sustain or are consonant with such harmony.

Such a conception of individual justice is virtue ethical because it ties justice (acting justly) to an internal state of the person rather than to (adherence to) social norms or to good consequences; but Plato's view is also quite radical because it at least initially leaves it an open question whether the just individual refrains from such socially proscribed actions as lying, killing, and stealing. Plato eventually seeks to show that someone with a healthy, harmonious soul wouldn't lie, kill, or steal, but most commentators consider his argument to that effect to be highly deficient.

Aristotle is generally regarded as a virtue ethicist par excellence, but his account of justice as a virtue is less purely virtue ethical than Plato's because it anchors individual justice in situational factors that are largely external to the just individual. Situations and communities are just, according to Aristotle, when individuals receive benefits according to their merits, or virtue: those most virtuous deserve more of whatever goods society is in a position to distribute (exemptions from various burdens or evils counting as goods). This desert-based conception of social justice then treats the virtue of individual justice as a matter of being disposed to properly respect and promote just social arrangements. An individual who seeks more than her fair share of various goods has the vice of greediness (pleonexia), and a just individual is one who has rational insight into her own deserts in various situations and who habitually (and without having to make heroic efforts to control contrary impulses) takes no more than what she deserves, no more than her fair share of good things. Since Aristotle treats all individual virtues as (learned dispositions) lying in a mean between extremes (courage, e. g., is between cowardice and foolhardiness), he also doesn't think it is virtuous to take less than one's fair share of things (though the issue is somewhat complicated for him).

However (and as William Frankena once noted), this account of justice seems circular or ungrounded, because if one's just deserts depend on how virtuous one is, the issue of what one's fair share is cannot be decided independently of whether one is being virtuous in actually taking some particular share and the latter issue, in turn, depends for Aristotle on one's being able to know independently what one's fair share is. We have reason to doubt, therefore, whether Aristotle has really given us a determinate conception of justice either as an individual or as a situational virtue.

Both Plato and Aristotle were rationalists as regards both human knowledge and moral reasons, and what they say about the virtue of justice clearly reflects the commitment to rationalism. Much subsequent thinking about justice (especially in the Middle Ages) was influenced by Plato and Aristotle and likewise emphasized the role of reason both in perceiving what is just and in allowing us to act justly rather than give in to contrary impulses or desires. But to the extent Christian writers allied themselves with Plato

and Aristotle, they were downplaying another central element in Christian thought and morality, the emphasis on agapic love. Such love seems to be a matter of motivationally active feeling rather than of being rational, and some writers on morality (eventually) allowed this side of Christianity to have a major influence on what they had to say about virtue.

In particular, the so-called moral sentimentalists Hutcheson and Hume (not to mention Shaftesbury and Adam Smith) treated morality as grounded in something other than reason, and the influence of Christian ideas and ideals of agapic love on Hutcheson (at least) is well documented. For Hutcheson, universal (i.e., impartial) benevolence is the highest and best of human motives, but we know this, not through reason, but through a moral sense (or sensitivity). Also, according to Hutcheson, the individual virtue of justice (ultimately) consists in being motivated by universal benevolence, and he explicitly denies that benevolence can ever conflict with true justice.

Hume saw (or believed he saw), however, that individual justice at least sometimes conflicts with what benevolence would motivate us to do. He is as much as sentimentalist as Hutcheson, believing that judgments about virtue and rightness depend on our capacity for sympathy rather than on some form of reason (or on a distinct moral sense) and holding that being virtuous depends on feelings and feelingful motives like benevolence and sympathy rather than on reason. But he thinks that the sentimentalist owes us an account of how a sense of justice that is sometimes opposed to benevolence and sympathy can nonetheless develop out of such motives. Motives like benevolence, curiosity, and prudence Hume calls natural in the twofold sense that they exist apart from social convention(s) and that they do not require explicitly ethical thinking (or conscience) or in order to issue in action. But the virtue of justice is not natural, but rather should be considered "artificial," according to Hume, because it depends for its existence on human conventions and artifices and because the primary motive to justice is a sense of justice (or of duty).

Now Hume thinks of the individual virtue of justice quite narrowly as comprising a certain kind of respect for (other people’s) property. The just person doesn’t steal from others and returns what he has borrowed (and Hume points out the similarity of this usage to the Aristotelian notion that justice consists in everyone getting his due, what he deserves). But there are other artificial virtues, according to Hume, among them, fidelity to promises (keeping one’s promises), law-abidingness, and (female) modesty/chastity. Hume thinks that it is difficult to account for any one, or all, of these artificial virtues in (his own) empiricist anti-rationalist terms, and there are at least two reasons for this.

One has to do with the inadequacy of natural motives like benevolence or prudence for grounding the requirements of justice. In primitive or simple societies, there may always be reasons of prudence to act justly with respect to the property of others: violations of justice are always likely to be detected by others and to lead to consequences one would prefer to avoid. In such circumstances honesty (a term Hume tends to use narrowly as synonymous with "justice") really is the best policy. Furthermore, within the narrow confines of a small group, personal affection and benevolent concern for those one knows and lives with may lead one to refrain from violations of their property. But in a larger (and more advanced) society, things will be different.

In large-scale modern societies (of the sort Hume lived in) we may not know our neighbors, much less all those people our actions might affect, and the people whose property justice calls on us to respect include a vast majority who don't know us either. Under conditions of such relative anonymity and complexity, the identity of a thief may be much more difficult to ascertain, and if one (knows one) can get away with stealing on some occasions, then prudence is presumably incapable of motivating a just refusal or unwillingness to steal. More importantly, perhaps, the conditions of a modern society leave us without strong ties of affection to many of the people we interact with or may affect by our actions, and Hume thinks that normal humanity or humane benevolence isn't a strong enough motive to get us to refrain from a theft that would greatly benefit ourselves or our families (those we do have strong affections toward). So if we refrain from such theft, we cannot explain or justify such refraining by reference to any actual natural motives.

But of course we do (many of us) justly refrain from taking or violating other people's property on occasions when natural motives as such may seem incapable of explaining why we do, and Hume believes (not uncommonsensically) that it is artificial motives or motivation that explain why we do so. Someone who can get away with stealing and who has stronger reasons/motives of affection to steal than not to steal may nonetheless refrain from stealing because she thinks it unjust or wrong to steal. A sense of duty or conscience is thus for Hume absolutely essential to understanding the virtue and obligation of justice/honesty.

Moreover, and this is perhaps the most important point for Hume, even if human beings were capable of the strong universal/impartial benevolence that Hutcheson regarded as the cornerstone of moral virtue, such benevolence would not in all instances suffice for us to fulfill our intuitive obligations of justice. Justice and moral obligation sometimes seem opposed to the dictates of (what would be motivated by) universal benevolence, and Hume cites one's obligation (of justice) to return what one owes to a "seditious bigot" as one glaring instance of this point. Concern for the good of society or of humanity would presumably dictate that one not return to the bigot money or property he would use to subvert and corrupt society or the state, but, according to Hume, we nonetheless think it obligatory to return what we owe, and what gets us to do so, therefore, is a(n artificial) sense of duty (or justice) rather than any (even hypothetically imaginable) natural motive.

It is possible to question this, and Bentham, for example, claimed that his disagreement with Hume's view of our actual obligations in such cases was what initially led him to utilitarianism. However, the idea that we should return the money or property despite what free-wheeling prudence or benevolence would lead us to do is intuitively forceful, and Hume shows himself aware of the potential clash here between benevolence and justice/morality in a way that Hutcheson was not. Moreover, I am dwelling at some length on Hume in part because the question of whether justice can be understood entirely in terms of natural motives is (as Hume rightly saw) absolutely crucial to understanding the nature of justice as an individual (or, for that matter, social) virtue.

Now if we agree that the right and just thing to do in cases like that of the seditious bigot is to return what one owes, then the importance of artificial motives looms large. But this leaves Hume with a

problem (or a set of problems). Hume is an empiricist and an anti-rationalist who emphasizes feeling/sentiment as the basis of morality. But if natural motives can't explain the virtue of justice, then the sentimentalist owes us an account of how a sense of duty, obligation or justice develops. (For the moment, I leave aside the other artificial virtues, which raises similar issues.) Rationalists tend to think of the sense of duty as a response of reason to certain moral facts or relations, so if Hume is to maintain his sentimentalism, he needs (among other things) to explain to us (in terms compatible with his empiricist premises) how a sense of duty develops out of (or can exist as a) feeling or feelingful motivation. And, as is well known, Hume finds this extremely difficult to do.

Hume seeks to explain moral judgment and a sense of duty or conscientiousness based in such judgment in terms of the same mechanisms of sympathy that operate within and through the natural virtues. However, we tend to be more sympathetic with those near and dear to us, and moral judgment seeks or presupposes some sort of impartiality regarding those affected by or engaging in actions (it is no more wrong for someone to kill a member of my family than for someone to kill someone I don't know). So Hume argues that we in various ways (try to) correct for personal (or temporal) bias when making moral judgments and take, in particular, the view of a sympathetic but impartial spectator in doing so. But this still can't explain why we should in all conscience and justice return what we owe to the seditious bigot--here the most extensive and impartial sympathy would seem to dictate acting for the greatest happiness rather than justly in Hume's terms. (The utilitarian typically regards acting for the greatest happiness as the essence of true justice, but the point remains that we intuitively regard justice as *conflicting* with the dictates of utilitarianism in the kind of case just mentioned.)

Hume goes through a number of (what seem to me and many others to be) contortions in an effort to explain the possibility of (anti-benevolent) conscientiousness and justice (or promise keeping, etc.). At times, he seems to think parents or educators can influence (or even psychologically force) children to disapprove of injustice (even when it promotes the general happiness). But this presupposes, I believe, that the parents and educators already themselves have acquired such a strict sense of conscientiousness, whereas it is not clear in the first place that or how Hume's theory allows this to happen. And it is also not clear how such disapproval, either in the children or in the parents/educators, can be inculcated via the mechanisms of sympathy (or immediate agreeability) that Hume says are required for moral approval and judgment.

Matters get even more problematic for Hume's theory of justice and the other artificial virtues because Hume makes it clear that he is (what we would call) a virtue ethicist. He says that the moral status of an action depends entirely on the goodness or badness of the motive that lies behind it, so that, e. g., it is only because certain helpful actions were intended to be helpful (were motivated by the natural virtue of benevolence) that we morally approve of them or judge them to be right and good. However, it is difficult to apply this virtue-ethical assumption to the artificial virtues, because the good motive operative in their instance is *the conscientious desire to do one's duty or what is right or obligatory*. According to Hume, if I return what I owe to the seditious bigot, my only just motive is the desire to do what is right and obligatory, but, in that case, the morally good motive that is supposed (according to Hume's virtue ethics) to *explain* the rightness or goodness of returning what I owe to the seditious bigot *already makes essential reference to the rightness or goodness or obligatoriness of doing so*. As Hume

himself tells us, this seems to be arguing (explaining) in a circle, and Hume makes the same point (perhaps even more forcefully) about fidelity to promises. Although some subsequent commentators think Hume has a way out of this circle, many have not thought this to be possible (I tend to agree with them), and if that is so, then Hume's attempt to justify or explain justice as an individual virtue via empiricist sentimentalist (associationist) mechanisms cannot succeed.

2. Rationalism and Justice

Such a conclusion has led many subsequent ethical thinkers to think that justice cannot be based in sentiment but requires a more intellectually constructive rational(ist) basis, and in recent times this view of the matter seems to have been held, most influentially, by John Rawls in *A Theory of Justice*. Rawls makes clear his belief in the inadequacy of benevolence or sympathetic human sentiment in formulating an adequate conception of social justice. (He says in particular that sentiment leaves unanswered or indeterminate various important issues of justice that a good theory of justice ought to be able to resolve).

Rawls's positive view of justice is concerned primarily with the justice of institutions or (what he calls) the "basic structure" of society: justice as an individual virtue is derivative from justice as a social virtue defined via certain principles of justice. The principles, famously, are derived from an "original position" in which (very roughly) rational contractors under a "veil of ignorance" decide how they wish to commit themselves to being governed in their actual lives. Rawls deliberately invokes Kantian rationalism (or anti-sentimentalism) in explaining the intellectual or theoretical motivation behind his construction, and the two principles of justice that he argues would be agreed upon under the contractual conditions he specifies represent a kind of egalitarian political liberalism. Roughly, those principles stress (equality of) basic liberties and opportunities for self-advancement over considerations of social welfare, and the distribution of goods in society (according to the the so-called difference principle) is then supposed to work to the advantage of all (especially the worst-off members of society). Rawls argues that a utilitarian principle of justice dictating simply the maximization of overall social well-being would not be accepted in his original position and is accordingly less plausible than the conception of justice embodied in his own two principles and the construction that leads to them. He also says that the idea of what people distributively deserve is derivative from social justice rather (as with Aristotle and much common-sense thinking) providing the basis for thinking about social justice.

However, it is not merely social justice that Rawls understands in (predominantly) rationalist fashion. When he explains how individuals (within a just society) develop a sense and/or the virtue of justice, he invokes the work of Piaget, who saw moral development as akin to the other sorts of development he so famously studied. Those other sorts were of course various forms of cognitive or intellectual development, and Piaget treats moral development, therefore, as principally involving increasing cognitive sophistication. More particularly, Piaget sees that sophistication as a matter of taking more and more general or universal views of moral issues, and the Kantian and rationalist idea that morality rests on and can be justified in terms of considerations of universality (if it is right for me, it is right for everyone similarly situated) or universalizability (could I will this to be a rule governing everyone's actions?) seems to underlie or to be presupposed in much that Piaget says about moral development.

Now Rawls lays more stress than Piaget does on the role our affective nature (sympathy and the desire for self-mastery) plays in the acquisition of moral virtue. But, like Piaget, he stresses the need for a *sufficiently general appreciation and rational understanding* of social relations as the grounding basis of sense of duty or of justice and he explicitly classifies his account of moral development as falling within the "rationalist tradition." Rawls also gives distinct arguments for believing that it is rational to *retain and act upon* a sense of justice.

According to Rawls, individual justice is theoretically derivative from social justice because the just individual is to be understood as someone with an effective or "regulative" desire to comply with the principles of justice. This makes the individual virtue of justice an artificial one in Hume's sense, but, in part because he doesn't assume virtue ethics, Rawls doesn't get caught up in the Humean circle we described above. Other questions about Rawls's rationalist account of the virtue of justice, however, can lead us back in the direction of a non-circular and non-Humean form of *sentimentalism* about that virtue.

3. Stages of Moral Development

Rawls is far from the only thinker to conceive of moral development in terms substantially derived from Jean Piaget's work, and at the time Rawls was writing *A Theory of Justice*, educational psychologist Lawrence Kohlberg was working out a Piaget-inspired conception of moral development that postulated six stages of normal human moral development. Kohlberg claimed that the highest stage of such development involves a concern for justice and human rights based on universal principles and he relegated sheer concern for relationships and for individual human well-being to lower stages of the process. Moreover, he saw the ordering of the different stages in Piagetian fashion as basically reflecting differences in rational understanding: those whose moral thinking involved the invoking of universal principles of justice and rights were said to show a more advanced cognitive development than those whose moral thought appeals primarily to the importance of relationships and of human well-being or suffering.

This treats utiltarianism as less cognitively advanced (more primitive) than rationalist views like Rawls's and Kant's, and utilitarians (like Hare) have naturally called into question the objectivity and intellectual fairness of Kohlberg's account. (In fact, Rawls also questions whether any purely psychological theory of moral development could ever undercut utilitarianism in the way Kohlberg sought to do.) More significantly, perhaps, the evidence for Kohlberg's stage sequence was drawn from studies of boys, and when one applies the sequence to the study of young girls, it turns out that girls on average end up at a less advanced stage of moral development than boys do.

What came next is well known. In her 1982 book *In a Different Voice: Psychological Theory and Women's Development,* Carol Gilligan responded to Kohlberg's views by questioning whether a theory of moral development based solely on a sample of males could reasonably be used to draw conclusions about the inferior moral development of women. Gilligan argued that her own studies of women's development indicated that the moral development of girls and women proceeds and ends in a different

fashion from that of boys and men, but that that proves nothing about inferiority or superiority: it is merely a fact of difference. In particular, Gilligan claimed that women tend to think morally in terms of connection to others (relationships) and in terms of caring about (responsibility for) those with whom they are connected; men, by contrast and in line with Kohlberg's studies, tend to think more in terms of general principles of justice and of individual rights against (or individual autonomy from) other people.

4. Caring and Justice

Subsequently, many have questioned the empirical validity or accuracy of the studies Gilligan relied upon, but others have pointed out that the idea of a "different voice" need not be tied to specific assumptions about differences between the sexes. The voice of justice and principle represents a different style of moral thinking (and of an overall moral life) from that of caring for and connection with others, and later writers (notably Nel Noddings, but also Gilligan herself in later work) have tried to elaborate what a morality (moral life) based in caring would be like and also to show that such a morality may be superior to that embodied in traditional thinking about justice and rights and universal(izable) moral principles.

The primary fulcrum for articulation of any ethic of caring seems to lie in an ideal that stresses connection over separateness. The Kantian emphasis on the autonomy of the moral person and the Rawlsian/contractarian assumption of separate individuals coming together to forge a social contract see us a basically separate from others, whereas an ideal of caring concern for others sees our (initial) actual historical and personal connections with others as the basis for a positive and caring response to such connection. (However, an ethic of caring doesn't favor social conservatism in the way much communitarian thought does: any social structure that shows insufficient concern for one group or another can arguably be criticized via the ideal of mutual caring.)

In addition, an ethic of justice and rights tells us to regulate our actions or lives in accordance with certain general moral principles (or explicitly moral insights), whereas the ethic of caring stresses the good of a concern for the welfare of others that is *unmediated by principles, rules, or judgments that tell us that we ought to be concerned about their welfare*. In an ethic of caring, therefore, caring is treated as a natural virtue in Hume's sense, but this further highlights the way in which such an ethic involves us in connection with, rather than separateness from, other people. If we are concerned about others on the basis of a conscientious desire to do our duty or adhere to certain moral principles, then our concern for them is mediated by moral thinking, and someone, therefore, who cares about the welfare of others without having to rely on or be guided by explicit moral principles (or thinking) is more connected with those others than someone who acts only on the basis of such mediating principles (or thought). So the ethic of caring stresses connection with others both in what it says about the normative basis of morality and in what it says about the ways in which moral goodness shows itself within a morally good life; and by the same token, traditional Kantian or contractarian views of rights and justice give a double importance to separateness or autonomy from others through the grounds they adduce for moral/political obligation and the stress they place on being guided by moral principles or judgments within the moral life.

As I indicated above, defenders of an ethic of caring have increasingly come to view caring as grounding (offering a normative basis for) morality as a whole. That means that ideas about justice and rights either have no validity or can actually be reinterpreted and given an arguably firmer justification in terms of (what we originally regarded as the opposed notion of) caring. But it is difficult to believe that morality can properly or plausibly be confined to intimate relations of caring. For better or worse, we have to learn to live together in larger social units, and we cannot be intimate or even acquainted with every human being whose actions and fate are morally significant for us. So an ethic of caring that seeks to account for individual and social morality generally needs to say something in its own voice about social and international justice and about how given individuals can realize the virtue of justice.

In answer to this more or less explicit challenge, some caring ethicists have highlighted potential analogies between the way a mother cares for her children and the kinds of care a government, state, or society can offer to its citizens or inhabitants (who presumably cannot provide everything they need and want on their own). Others have noted that the notion of caring doesn't have to be restricted to close personal relationships and that one can intuitively speak of caring, in humanitarian fashion, about people one doesn't know (except by description). This then allows there to be obligations of caring both toward near and dear and toward humanity more generally, though the issue of how to balance these concerns becomes very important at that point.

But all these ways of developing and extending an ethic of caring seem united in stressing (what Hume calls) natural motives over artificial ones. If someone who doesn't care about his family or about human beings in general, always fails to act helpfully toward others, he exhibits a lack of caring, and an ethic of caring regards acts which display such morally deficient motivation as morally criticizable and wrong. This is virtue ethical because, as with Hume, the criterion of the rightness of an action has to do with the inner state or motive that lies behind it. But by the same token individuals who demonstrate the virtue of caring act in ways that show how much they care or are concerned about others, in ways that demonstrate their emotional connectedness with others, and this means in particular that such people don't have to remind themselves of moral ideals and obligations in order to get themselves to help those they care about. They help because they care, not because conscience or some sort of (abstract) love of the Good tells them (how virtuous or dutiful it would be) to do so.

But is this sort of natural virtue really adequate to those moral/political concerns that transcend intimate personal relationships? Hume didn't think so, and it is certainly not obvious on the face of it how an ethic of caring could handle such issues. Still, Hume makes things difficult for natural virtue by conceiving individual and social justice in highly conservative terms. According to Hume we have a strict obligation of justice to allow people to keep what they have earned through their own diligence and ingenuity rather than (say) tax it away (or, presumably, force unionization on factory owners). And since (given facts about diminishing marginal utility that Hume himself assumes to be familar to us) progressive taxation and the closed union shop arguably are on the whole good for society and known to be so, the natural motive of benevolent concern for the welfare of one's society might actually lead in the direction of genuine social justice. But such justice would then have to be conceived in less austerely rigid and more humane terms than those assumed and relied on by Hume.

However, when it comes to the individual virtue of justice, Hume himself supplies some of the means toward a (virtue-ethical) account relying solely on natural virtue (and thus not subject to "Hume's circle"). He points out that it is easier to bear not having (or being given) something than to bear having something taken away from one (thus anticipating what later psychologists have said about "adaptation levels"). And this in and of itself gives someone who is benevolent or caring about the well-being of others some reason (or motive) not to steal or allow stealing from others. However, there is also the fact that stealing (as opposed to merely allowing a theft to occur) is a positive commission, and a natural virtues approach to individual justice (vis-a-vis property) would certainly be helped along, if the distinction, say, between commission and omission, or between doing and allowing, could somehow be captured in *non-artificial* or *natural* sentimentalist terms.

This seems a tall order, and in fact the suspicion or belief that only rationalism can account for such distinctions (as, e. g., in Kant's "formula of humanity") may represent one of the largest challenges a sentimentalist ethic of caring needs to face. (Hume doesn't focus on the commission/omission distinction, although, in any event, his artificial virtues approach to the remaining aspects of deontology may at this point seem a dead end.) My own belief is that sentimentalism is up to this challenge because of the way caring about and for others is grounded in naturally developing human empathy.

Normal human caring isn't impartial (in the manner of "universal benevolence"), because it is easier to empathize with those near and dear to us, i. e., those with whom we share thoughts, lives, roots, or familial (or ethnic or national) traditions. But recent psychological studies of empathy and its relation to altruism indicate that we also tend to empathize more with those whose problems are immediate for us. We respond more to a child drowning right before our eyes than to the plight of a child we don't see and whom we know (only by description) to be in danger of dying of starvation in some distant country; and, similarly, we respond more to the "clear and present" danger faced by miners we hear are trapped underground than to dangers we know will arise in some indefinite future.

But if such perceptual and temporal immediacy make such differences (respectively) to empathic concern for others, it is arguable that causal immediacy does as well. The harm I could cause is more immediate for me than harm that I might merely allow to occur. We naturally flinch from (inflicting) the former more than from (allowing) the latter, and I say "naturally" because, as with cases involving perceptual or temporal immediacy, this is not a matter of being guided by moral principles or strictures, but of responsiveness to non-moral situational differences. If we are in this way more sensitive and responsive to differences in the strength of our potential causal relation to some harm or evil, then a moral sentimentalism that restricts itself to natural virtues may possess the resources to distinguish between commission and omission, and it may be able to use that distinction (among other things) to explain why stealing, promise-breaking, and killing are worse than allowing others to do these things. This might well then allow such an approach to account for the virtue of individual justice more successfully than Hume's theory of artificial virtues can.

5. Conclusion

In any event, there are many different conceptions of the virtue of justice, and only some of them are distinctively virtue ethical. Many non-virtual ethical approaches put forward theories of virtue, and what distinguishes them from virtue ethics is that the given theory of virtue comes later in the order of explanation, rather than itself serving as the basis for understanding (all of) morality. Rawls's conception of justice as an individual virtue is a good example of a non-virtue-ethical account of a virtue, since, as we saw, it treats individual justice as a matter of accepting and complying with independently defended moral/political principles or rules. I have tried above to offer a representative sampling of the variety of possible views about justice as a virtue, but if we have learned anything from the history of philosophy, we ought to recognize that there are probably other ways of conceiving the virtue of justice we haven't yet thought of.

George Santayana

Philosopher, poet, literary and cultural critic, George Santayana is a principal figure in Classical American Philosophy. His naturalism and emphasis on creative imagination were harbingers of important intellectual turns on both sides of the Atlantic. He was a naturalist before naturalism grew popular; he appreciated multiple perfections before multiculturalism became an issue; he thought of philosophy as literature before it became a theme in American and European scholarly circles; and he managed to naturalize Platonism, update Aristotle, fight off idealisms, and provide a striking and sensitive account of the spiritual life without being a religious believer. His Hispanic heritage, shaded by his sense of being an outsider in America, captures many qualities of American life missed by insiders, and presents views equal to Tocqueville in quality and importance. Beyond philosophy, only Emerson may match his literary production. As a public figure, he appeared on the front cover of *Time* (3 February 1936), and his autobiography (*Persons and Places*, 1944) and only novel (*The Last Puritan*, 1936) were the best-selling books in the United States as Book-of-the-Month Club selections. The novel was nominated for a Pulitzer Prize, and Edmund Wilson ranked *Persons and Places* among the few first-rate autobiographies, comparing it favorably to Yeats's memoirs, *The Education of Henry Adams*, and Proust's *Remembrance of Things Past*. Remarkably, Santayana achieved this stature in American thought without being an American citizen. He proudly retained his Spanish citizenship throughout his life. Yet, as he readily admitted, it is as an American that his philosophical and literary corpuses are to be judged. Using contemporary classifications, Santayana is the first and foremost Hispanic-American philosopher

1. Biography

Santayana's heritage is rooted in the Spanish diplomatic society with its stress on high education and familiarity with the world community. He was born in Madrid, Spain, on 16 December 1863. His father, Agustín Santayana, was born in 1812. The father studied law and practiced for a short time before entering the colonial service for posting to the Philippines. While studying law, Agustín served an apprenticeship to a professional painter of the school of Goya and a number of his paintings remain in the private possession of the family. He translated four Senecan tragedies into Spanish, wrote an unpublished book about the island of Mindanao, had an extensive library, and made three trips around the world. In 1845, he became the governor of Batang, a small island in the Philippines. He took over the governorship from the recently deceased José Borrás y Bofarull, who was the father of Josefina Borrás, later to become Agustín's wife in 1861 and the mother of George Santayana. His mother, Josefina Sturgis (formerly Josefina Borrás y Carbonell), was born in Scotland and was the daughter of a Spanish diplomat. Previously she married George Sturgis (d. 1857), a Boston merchant, whose early death left her alone with children in Manila. There were five children from this first marriage, three of whom survived infancy. She promised her first husband to raise the children in Boston where she moved her family. During a holiday in Spain, Josefina met Agustín again, and they were married in 1861. He was fifty years of age and she was probably thirty-five. In 1863, Santayana was christened Jorge Agustín Nicolás Ruiz de Santayana y Borrás. His half sister, Susan, insisted that he be called "George," after her Boston father. Santayana, in turn, always referred to his sister in the Spanish, "Susana."

1863-1886. Santayana lived eight years in Spain, forty years in Boston, and forty years in Europe. In his autobiography, *Persons and* Places, Santayana divides his life into three phases. The background (1863-1886) encompasses his childhood in Spain through his undergraduate years at Harvard. The second period (1886-1912) is that of the Harvard graduate student and professor with a trans-Atlantic penchant for traveling to Europe. The third period (1912-1952) is the retired professor writing and traveling in Europe and eventually establishing Rome as his home.

The family moved from Madrid to Ávila where Santayana spent his boyhood. In 1869, Santayana's mother left Spain in order to raise the Sturgis children in Boston, keeping her pledge to her first husband. In 1872, his father realized the opportunities for his son were better in Boston, and he moved there with his son. Finding Boston inhospitable, Puritanical, and cold, the father returned alone to Ávila within a few months. The separation between father and mother was permanent. In 1888 Agustín wrote to Josefina: "When we were married I felt as if it were written that I should be reunited with you, yielding to the force of destiny. Strange marriage, this of ours! So you say, and so it is in fact. I love you very much, and you too have cared for me, yet we do not live together" (*Persons and Places*, 9).

Until his father's death (1893), Santayana regularly corresponded with his father and he visited him after Santayana's first year at Harvard College. In Boston, Santayana's family spoke only Spanish in their home. Santayana first attended Mrs. Welchman's Kindergarten to learn English from the younger children, then he was a student at the Boston Latin School, and he completed his B.A. and Ph.D. at Harvard College (1882-1889), including eighteen months of study in Germany on a Walker Fellowship. His undergraduate years at Harvard reveal an energetic student with an active social life. He was a member of eleven organizations including *The Lampoon* (largely as a cartoonist), the *Harvard Monthly* (a founding member), the Philosophical Club (President), and the Hasty Pudding.

Some scholars conclude that Santayana was an active homosexual based on allusions in Santayana's early poetry (McCormick, 49-52) and Santayana's association with known homosexual and bisexual friends. Santayana provides no clear indication of his sexual preferences, and he never married. Attraction to both women and men seems apparent in his undergraduate and graduate correspondence. The one documented comment about his homosexuality occurs when he was sixty-five. After a discussion of A. E. Housman's poetry and homosexuality, Santayana remarked, "I think I must have been that way in my Harvard days -- although I was unconscious of it at the time" (Cory, *Santayana: The Later Years*, 40). Because of Santayana's well-known frankness, many scholars consider Santayana a latent homosexual based on this evidence.

1886-1912. Santayana received his Ph.D. from Harvard in 1889 and became a faculty member at Harvard University (1889-1912) and eventually a central figure in the era now called Classical American Philosophy. He was a highly respected and popular teacher, and his students included poets (Conrad Aiken, T. S. Eliot, Robert Frost, Wallace Stevens), journalists and writers (Walter Lippmann, Max Eastman, Van Wyck Brooks), professors (Samuel Eliot Morison, Harry Austryn Wolfson), a Supreme Court Justice (Felix Frankfurter), many diplomats (including his friend Bronson Cutting), and a university president (James B. Conant). He retired from Harvard in 1912 at the age of forty-eight and lived the remainder of his life in England and Europe, never returning to the U.S. and rejecting academic posts offered at a number of universities, including Harvard, Columbia, and Cambridge.

Santayana cherished academic life for its freedom to pursue intellectual interests and curiosity, but he found that many aspects of being a professor infringed on that freedom. Faculty meetings and university committees seemed primarily partisan heat over false issues, so he rarely attended them. The general corporate and businesslike adaptation of universities was increasingly less conducive to intellectual development and growth. He expressed concern about the evolving Harvard goal of producing muscular intellectuals to lead America as statesmen in business and government. Were not delight and celebration also a central aspect of education? He wrote to a friend in 1892, expressing the hope that his academic life would be "resolutely unconventional" and noted that he could only be a professor *per accidens*, saying that "I would rather beg than be one essentially" (GS to H. W. Abbot, Stoughton Hall, Harvard, 15 February 1892. Columbia).

In 1893, Santayana experienced a *metanoia*, a change of heart. Gradually he altered his style of life from that of an active student turned professor to one focused on the imaginative celebration of life. In doing so, he began planning for his early retirement, finding university life increasingly less conducive to intellectual pursuits and delight in living. Three events preceded his *metanoia*: the unexpected death of a young student, witnessing his father's death, and the marriage of his sister Susana. Santayana's reflections on these events led to the ancient wisdom that acceptance of the tragic leads to a lyrical release. "Cultivate imagination, love it, give it endless forms, but do not let it deceive you. Enjoy the world, travel over it, and learn its ways, but do not let it hold you … . To possess things and persons in idea is the only pure good to be got out of them; to possess them physically or legally is a burden and a snare (*Persons and Places*, 427-28)."

Increasingly, naturalism and the lyrical cry of human imagination became the focal points of Santayana's life and thought. Pragmatism, as developed by Peirce and James, was an undercurrent in his naturalism, particularly as an approach to how we ascertain knowledge, but there are aspects of his naturalism more aligned with European and Greek thought that presage developments in the late twentieth century. His naturalism had its historical roots primarily in Aristotle and Spinoza and its contemporary background in James's pragmatism and Royce's idealism. His focus on and celebration of creative imagination in all human endeavors (particularly in art, philosophy, religion, literature, and science) is one of Santayana's major contributions to American thought. This focus, along with his Spanish heritage, Catholic upbringing, and European suspicion of American industry, set him apart in the Harvard Yard.

Santayana's strong interest in literature and aesthetics is evident throughout this early period, but by 1904, his attention turned almost fully to philosophical pursuits. During this period his publications include: *Lotze's System of Philosophy* (dissertation), *Sonnets and Other Verses* (1894), *The Sense of Beauty* (1896), *Lucifer: A Theological Tragedy* (1899), *Interpretations of Poetry and Religion* (1900), *A Hermit of Carmel, and Other Poems* (1901), *The Life of Reason* (five books, 1905-1906), *Three Philosophical Poets: Lucretius, Dante, and Goethe* (1910).

In May 1911, Santayana formally announced his long-planned retirement from Harvard. President Lowell asked him to reconsider. By now Santayana was a highly recognized philosopher, cultural critic, poet, and teacher, and his desire to be free from academic confinement was also well known. Lowell indicated he was open to any arrangement that provided Santayana the time he desired for writing and for travel in Europe. Initially Santayana agreed to alternate years in Europe and the U.S., but in 1912, his resolve to retire overtook his sense of obligation to Harvard. The year before his retirement, he had presented at least six lectures at a variety of universities including Berkeley, Wisconsin, Columbia, and Williams. His books were selling well and his publishers were asking for more. Two major universities were courting him. At forty-eight, he left Harvard to become a full-time writer and to escape the academic professionalism that nurtured a university overgrown with "thistles of trivial and narrow scholarship."

1912-1952. As Santayana sailed for Europe, his mother died, apparently of Alzheimer's disease. Always attentive to his family, Santayana visited her weekly, then daily, during his last years at Harvard. Knowing his mother's death was imminent, he arranged for Josephine, his half sister, to live in Spain with Susana, who previously had married a well-to-do Ávilan. An inheritance of $10,000 from his mother, coupled with his steady income from publications and his early planning, made retirement easier. He arranged for his half brother, Robert, to manage his finances with the agreement that upon Santayana's death, Robert or his heirs would receive the bulk of Santayana's estate. Hence, in January 1912, at age forty-eight, Santayana was free from the constraints of university regimen and expectations and, more importantly, free to write, to travel, and to choose his residence and country.

Santayana's book publications after leaving Harvard is remarkable: *Winds of Doctrine* (1913), *Egotism in German Philosophy* (1915), *Character and Opinion in the United States* (1920), *Soliloquies in England and Later Soliloquies* (1922), *Scepticism and Animal Faith* (1923), *Dialogues in Limbo* (1926),

Platonism and the Spiritual Life (1927), the four books of *The Realms of Being* (1927, 1930, 1938, 1940), *The Genteel Tradition at Bay* (1931), *Some Turns of Thought in Modern Philosophy* (1933), *The Last Puritan* (1935), *Persons and Places* (1944), *The Middle Span* (1945), *The Idea of Christ in the Gospels* (1946), *Dominations and Powers* (1951), and *My Host the World* (1953, posthumous).

Harvard attempted to bring him back to the United States, offering him several professorships beginning in 1917. As late as 1929, he was offered the Norton Chair in Poetry, one of Harvard's most respected chairs. In 1931, he received an invitation from Brown University, and Harvard later asked him to accept the William James Lecturer in Philosophy, a newly established honorary post. But Santayana never returned to Harvard or to America. Believing that the academic life was not a place for him to cultivate intellectual achievement or scholarly work, Santayana also refused academic appointments both at Oxford University and Cambridge University.

At first, Santayana planned to reside in Europe, and after numerous exploratory trips to several cities, he decided on Paris. However, while he was in England, World War I broke out and he was unable to return to the mainland. First, he lived in London and then primarily at Oxford and Cambridge. After the war, he was more of a traveling scholar, and his principal locales included Paris, Madrid, Ávila, the Riviera, Florence, and Rome. By the late 1920s, he settled principally in Rome, and during the summers, he often retreated to Cortina d'Ampezzo in northern Italy to write and to escape the heat. Because of his success as a writer, he assisted friends and scholars when they found themselves in need of financial support. For example, when Bertrand Russell was unable to find a teaching post in the U.S. or England because of his views regarding pacifism and marriage, Santayana displayed a characteristic generosity in his plan to make an anonymous gift to Bertrand Russell of the $25,000 royalty earnings from *The Last Puritan*, at the rate of $5,000 per year, in the letter to George Sturgis (15 July 1937). Despite the fact that he and Russell disagreed radically both politically and philosophically, his memory of their earlier friendship and his regard for Russell's genius moved him to compassion for Russell's financial plight.

The rise of Mussolini in the 1930s initially seemed positive to Santayana. He viewed the Italian civil society as chaotic and thought Mussolini might bring order where needed. But Santayana soon noted the rise of a tyrant. Trying to leave Italy by train for Switzerland, he was not permitted to cross the border because he did not have the proper papers. With most of his funds coming from the United States and England, his case was complicated by his Spanish citizenship and his age. He returned to Rome, and on 14 October 1941 he entered the Clinica della Piccola Compagna di Maria, a hospital-clinic run by a Catholic order of nuns, where he lived until his death eleven years later. This arrangement was not unusual. The hospital periodically received distinguished guests and cared for them in an assisted-living environment. Santayana died of cancer on 26 September 1952.

Santayana asked that he be buried in unconsecrated ground, affirming his naturalism to the end. However, the only such cemetery ground in Rome was reserved for criminals. The Spanish Consulate at Rome would not permit Santayana to be buried in such a place and provided the "Panteon de la Obra Pia espanola" in the Campo Verano cemetery as a suitable burial ground, turning it into a memorial for the lifelong Spanish citizen. At the graveside, Daniel Cory read lines from Santayana's "The Poet's Testament," a poem affirming his naturalistic outlook:

> I give back to the earth what the earth gave,
> All to the furrow, nothing to the grave.
> The candle's out, the spirit's vigil spent;
> Sight may not follow where the vision went.

In the United States, Wallace Stevens commemorated his teacher in "To an Old Philosopher in Rome."

> Total grandeur of a total edifice,
> Chosen by an inquisitor of structures
> For himself. He stops upon this threshold,
> As if the design of all his words takes form
> And frame from thinking and is realized.

2. Philosophy, Literature, and Culture

Throughout his life, Santayana's literary achievements are evident. As an eight-year-old Spaniard, he wrote *Un matrimonio* (A Married Couple), describing the trip of a newly married couple that meets the Queen of Spain. Later in Boston, he wrote a poetic parody of *The Aeneid*; "A Short History of the Class of '82"; and "Lines on Leaving the Bedford St. Schoolhouse." His first book, *Sonnets and Other Verses* (1894), is a book of poems, not philosophy. And, until the turn of the century, much of his intellectual life was directed to the writing of verse and drama. He was a principal figure in making modernism possible but was not a modernist in poetry or literature. His naturalism and emphasis on constructive imagination influenced both T. S. Eliot and Wallace Stevens. Eliot's notion of the "objective correlative" is drawn from Santayana, and Stevens follows Santayana in his refined naturalism by incorporating both Platonism and Christianity without any nostalgia for God or dogma.

Santayana was among the leaders in transforming the American literary canon, dislodging the dominant Longfellow, Lowell, Whittier, Holmes, Bryant canon. Santayana's essay "The Genteel Tradition in American Philosophy" (presented to the Philosophical Union of the University of California in 1911) greatly affected Van Wyck Brooks's *America's Coming-of-Age*, a book that set the tone for modernism. Brooks drew on Santayana's essay, adapting Santayana's idea of two Americas to fit his notion of an America split between highbrow and lowbrow culture.

By the turn of the century, Santayana's interests largely centered on his philosophical inquiries, and although he never abandoned writing poetry, he no longer considered it his central work. Even so, some of his most moving poetry came later and was inspired by the trench warfare and casualties of World War I: "A Premonition: Cambridge, October, 1913"; "The Undergraduate Killed in Battle: Oxford, 1915"; "Sonnet: Oxford, 1916"; and "The Darkest Hour: Oxford, 1917." Throughout his life, even near death, he recited and translated long fragments of Horace, Racine, Leopardi, and others.

The relationships between literature, art, religion and philosophy are prominent themes throughout Santayana's writings. *The Sense of Beauty* (1896) is a primary source for the study of aesthetics. Philip Blair Rice wrote in the foreword to the 1955 Modern Library edition: "To say that aesthetic theory in America reached maturity with *The Sense of Beauty* is in no way an overstatement. Only John Dewey's *Art as Experience* has competed with it in the esteem of philosophical students of aesthetics and has approached its suggestiveness for artists, critics and the public which takes a thoughtful interest in the arts." Santayana's groundbreaking approach to aesthetics is emphasized in Arthur Danto's "Introduction" to the 1988 critical edition. Danto writes that Santayana brings "beauty down to earth" by treating it as a subject for science and giving it a central role in human conduct, in contrast to the preceding intellectualist tradition of aesthetics. "The exaltation of emotion and the naturalization of beauty -- *especially* of beauty -- imply a revolutionary impulse for a book it takes a certain violent act of historical imagination to recover" (*Sense of Beauty*, xxviii). This naturalistic approach to aesthetics is expanded in his philosophical explication of art found in *The Life of Reason: Reason in Art* (1905).

In 1900, Santayana's *Interpretations of Poetry and Religion* develops his view that religion and poetry are expressive celebrations of life. Each in its own right is of great value, but if either is mistaken for science, the art of life is lost along with the beauty of poetry and religion. Science provides explanations of natural phenomena, but poetry and religion are festive celebrations of human life born of consciousness generated from the interaction of one's psyche (the natural structure and heritable traits of ones physical body) and the physical environment. As expressions of human values, poetry and religion are identical in origin. Understanding the naturalistic base for poetry and religion and valuing their expressive character enable one to appreciate them without being hoodwinked: "poetry loses its frivolity and ceases to demoralise, while religion surrenders its illusions and ceases to deceive" (172). Interestingly, his father expressed similar views in his letters to his son, providing the genesis of his son's reflections, and this conclusion is expressed as late as the 1946 publication of *The Idea of Christ in the Gospels* where Santayana presents the idea of Christ as poetic and imaginative, contrasted with attempts at historical, factual accounts of the Christ figure. The impact of Santayana's view was significant, and Henry James (after reading *Interpretations of Poetry and Religion*) wrote that he would "crawl across London" if need be to meet Santayana.

Three Philosophical Poets (1910) was the first volume of the Harvard Studies in Comparative Literature. Santayana employs a naturalistic account of poetry and philosophy, attempting to combine comparative structures with as few embedded parochial assumptions as possible while making explicit our material boundness to particular worlds and perspectives. His analyses of Lucretius, Dante, and Goethe are described by one biographer as "a classical work and one of the few written in America to be genuinely comparative in conception and execution, for its absence of national bias and its intellectual, linguistic, and aesthetic range" (McCormick, 193).

Initially, Santayana appears optimistic about the youthful America. In his Berkeley lecture, "The Genteel Tradition in American Philosophy," he declared "the American Will inhabits the sky-scraper; the American Intellect inhabits the colonial mansion." ("The Genteel Tradition in American Philosophy," Triton Edition, vol. VII. P. 129.) European transcendentalism and Calvinism are the American intellectual traditions, but they no longer suit the American drive for success in industry, business, and

football. Hence, the youthful willfulness of the country has outrun the old wits, but there remains a chance for wisdom and energy to be coupled in a future coherent and rich tradition, and he sees the beginnings of such a tradition in James's pragmatism.

Within a decade, he is less optimistic. *Character and Opinion in the United States* (1920) is his valediction to America. It includes frank, intellectual portraits of his Harvard colleagues and of American culture. From his residence in Cambridge, he praises the English emphasis on social cooperation and personal integrity and contrasts them with America where "You must wave, you must cheer, you must push with the irresistible crowd; otherwise you will feel like a traitor, a soulless outcast, a deserted ship high and dry on the shore … . This national faith and morality are vague in idea, but inexorable in spirit; they are the gospel of work and the belief in progress. By them, in a country where all men are free, every man finds that what most matters has been settled beforehand" (211).

Santayana's standing as a literary figure reached its zenith with the publication of *The Last Puritan* (1936). *The Last Puritan* is Santayana's only novel, and it was an international success. It was compared positively with Goethe's *Wilhelm Meister*, Pater's *Marius*, and Mann's *The Magic Mountain*. Its provenance lies in the 1890s when Santayana began a series of sketches on college life that, broadened through his experience and travel, resulted in *The Last Puritan*. Essentially, it is about the life and early death of an American youth, Oliver Alden, who is sadly restricted by his Puritanism. Santayana draws a sharp contrast with the European Mario, who delights in all matters without a narrow moralism. Mario is a carefree, naturally gifted and likeable young man who by American standards appears too focused on the peripheral aspects of life: travel, opera, love affairs, and architecture. And the American perspective is embodied in the tragic hero, Oliver Alden, who is the last puritan. He does what is right, based on his duties to his family, school, and friends. Life is a slow, powerful flow of tasks and responsibilities. He is intelligent and knows there is more than obligation, and he senses his guilt at not being able to achieve the natural abundant life, but knowing this only nourishes his Puritanism and causes him to feel guilty about being guilty. In a charming scene in the novel, Oliver introduces Mario to Professor Santayana at Harvard. Oliver is a dedicated student and football player, thoroughly a first rate American taking matters seriously and doing his best. After only a short visit with the Professor, Mario, it is decided by Santayana, does not need to take a course from the Professor. Mario already has the natural, instinctual approach of a cultivated person. Oliver, on the other hand, knows he must work to achieve his goal, which will be only a succession of goals, and ends tragically. Santayana's Hispanic and Catholic background play a central role in his critique of American life: too bound by past traditions and obligations that are not understood or rooted in one's own culture.

The fear that Santayana's autobiography would be lost or destroyed during World War II, led Scribner's, the publisher, to conspire with the U.S. Department of State, the Vatican, and the Spanish government to bring the manuscript of the first part (*Persons and Places*) out of Rome *sub rosa*, despite the Italian government's refusal to allow any mail to the U.S. The manuscript for the second part (*The Middle Span*, 1945) also was conveyed surreptitiously to New York. The third part (*My Host the World*, 1953) was published after Santayana's death. His autobiography provides the basis for understanding the development of his philosophy

3. Development of Santayana's Philosophy

In his autobiography, *Persons and Places*, Santayana describes the development of his thought as a movement from the idealisms of boyhood to the intellectual materialism of a traveling student, and finally to the complete, naturalistic outlook of the adult Santayana. He emphasizes the continuity of his life and beliefs, contrasting what may appear to be disparate views with the overall unity of his thought: "The more I change the more I am the same person" (*Persons and Places*, 159).

As a young man of the nineteenth century, he was influenced by the idealism of the age and of his age, but he claims to have always been a realist or naturalist at heart.

But those ideal universes in my head did not produce any firm convictions or actual duties. They had nothing to do with the wretched poverty-stricken real world in which I was condemned to live. That the real was rotten and only the imaginary at all interesting seemed to me axiomatic. That was too sweeping; yet allowing for the rash generalisations of youth, it is still what I think. My philosophy has never changed. (*Persons and Places*, 167)

Hence he notes, that in spite "of my religious and other day-dreams, I was at bottom a young realist; I knew I was dreaming, and so was awake. A sure proof of this was that I was never anxious about what those dreams would have involved if they had been true. I never had the least touch of superstition" (*Persons and Places*, 167). Santayana cites poems, "To the Moon" and "To the Host," written when he was fifteen or sixteen, as revealing this early realism, and he quotes from memory one stanza of "At the Church Door" where the realistic sentiment is the same (*Persons and Places*, 169).

By the time he was a traveling student seeing the world in Germany, England, and Spain his "intellectual materialism" was firmly established with little change in his religious affections.

From the boy dreaming awake in the church of the Immaculate Conception, to the travelling student seeing the world in Germany, England, and Spain there had been no great change in sentiment. I was still "at the church door". Yet in belief, in the clarification of my philosophy, I had taken an important step. I no longer wavered between alternative vies of the world, to be put on or taken off like alternative plays at the theatre. I now saw that there was only one possible play, the actual history of nature and of mankind, although there might well be ghosts among the characters and soliloquies among the speeches. Religions, all religions, and idealistic philosophies, all idealistic philosophies, were the soliloquies and the ghosts. The might be eloquent and profound. Like Hamlet's soliloquy they might be excellent reflective criticisms of the play as a whole. Nevertheless they were only parts of it, and their value as criticisms lay entirely in their fidelity to the facts, and to the sentiments which those facts aroused in the critic. (*Persons and Places*, 169)

The full statement and development of his materialism did not occur until later in his life. It was certainly in place by the time of *Scepticism and Animal Faith* (1923) but not fully so at the time of *The Life of*

Reason (1905). The influence of the Harvard philosophers, particularly James and Royce is evident in Santayana's thought, but he was hardly a mere follower and often advanced his philosophy more along European and Greek lines rather than the American tradition, which he thought was both too derivative and too tied to the advancement of business and capitalism.

The move from Harvard marked not only a geographical shift but a philosophical one as well. Henry Levinson in *Santayana, Pragmatism, and the Spiritual Life* provides a well-balanced account of this gradual but distinctive move from the Harvard philosophical mentality. Leaving Harvard also meant that Santayana abandoned the view of a philosopher as a public, philosophical statesman and of language as being representative. This philosophical turn placed makes him a forerunner of many issues in the next two centuries. Removing himself, literally and philosophically, from the American scene, Santayana increasingly came to believe that the "brimstone" sensibility of pragmatism was wrong-headed (*Character and Opinion in the United States*, 53). A major aspect of this sensibility was the view that philosophers must be engaged fundamentally in social and cultural policy formulation, and if they are not, they are not pulling their civic weight. In this fashion, Santayana believes the pragmatists came to belie "the genuinely expressive, poetic, meditative, and festive character of their vocation" (Levinson,165). A condition that James took seriously in his "On a Certain Blindness in Human Beings," suggesting that the world of practical responsibility fosters a blindness to multiplural ways of living that can only be escaped by catching sight of "the world of impersonal worths as such" -- "only your mystic, your dreamer, or your insolent loafer or tramp can afford so sympathetic an occupation" (James, *Talks to Teachers on Psychology and to Students on Some of Life's Ideals*, 141). Interestingly, America's imperialistic actions toward the Philippines during the Spanish-American War sparked James' remarks; this was a war that had a much deeper ancestral and historical aspect for Santayana and led to his poem, "Young Sammy's First Wild Oats." Whether connected or not, Santayana later came to identify himself as an intellectual vagabond or tramp, not isolated in the specific perspectives of an ideology, hosted by the world, and devoted to spiritual disciplines that "appear irresponsible to philosophers hoping to command representative or some otherwise privileged authority at the center of society" (Levinson, 167).

Building on his naturalism, institutional pragmatism, social realism, and poetic religion, Santayana on leaving Harvard moves even farther from the role of philosophical statesman by removing the representative authority of language from the quest for a comprehensive synthesis, by narrowing the line between literature and philosophy (as he had earlier done between religion and poetry), and by wrestling more with the influence of James than of Emerson. Santayana's stay in Oxford during the Great War led to his famous counter to Wilson's war to end all wars: "Only the dead have seen the end of war." (*Soliloquies in England and Later Soliloquies*, 102)

Santayana's message is clear: The epistemological project that Russell's *Problems* epitomizes is diseased. The renewed quest to establish unmediated Knowledge of Reality simply leads to "intellectual cramp" (*Soliloquies*, 216). Philosophy has itself become spiritually *disordered* by blinding its practitioners from their traditional and proper task, which is to celebrate the good life. If the spiritual disciplines of philosophy are to thrive, philosophers have to take off the bandages of epistemology and metaphysics altogether, accept the finite and fallible status of their knowledge claims, and get on with confessing their belief in the things that make life worth living. (Levinson, 204)

Leaving Harvard and America enabled Santayana to develop his naturalism.

4. Naturalism

Scepticism and Animal Faith (1923) introduces Santayana's mature naturalism. In summary, he maintains that knowledge and belief are not the result of reasoning. They are inescapable beliefs essential for action. Epistemological foundationalism is a futile approach to knowledge. A more promising approach is to discern the underlying belief structures assumed in animal action and imposed by natural circumstances. The foundations for this approach are rooted in Aristotle's concept of activity and the pragmatic approach to action and knowledge. Explanations of natural events are the proper purview of scientists, while explications of the meaning and value of action may be the proper sphere of historians and philosophers. Even so, both scientific explanation and philosophical explication are based in the natural world. Meaning and value are generated by the interaction of our physical makeup, which Santayana calls "psyche," and our material environment.

Santayana's critique of epistemological foundationalism is as unique as his heritage. With Spanish irony, he structures his argument after Descartes' *Meditations* but arrives at an anti-foundationalist conclusion. Drawing attention to what is given in an instant of awareness (the smallest conceivable moment of consciousness), he maintains that any knowledge or recognition found in such an instant would have to be characterized by a concept (or "essence" to use Santayana's term). Concepts cannot be limited to particular instances; rather the particular object is seen as an instance of the concept (essence). Thus, pursuing doubt to its ultimate end, one is confined by the "solipsism of the present moment." That is, in a single instant of awareness there can be no knowledge or belief, since both require concepts not bounded by a moment of awareness. Hence, the ultimate end of doubt, an instance of awareness, is empty. It is the vacant awareness of a given without a basis for belief, knowledge or action. Santayana concludes that if one attempts to find the bedrock of certainty, one may rest his claim only after he has, at least theoretically, recognized that knowledge is composed of instances of awareness that in themselves do not contain the prerequisites for knowledge, i.e., concepts, universals, or essences. That both skepticism and proofs against skepticism lead nowhere is precisely Santayana's point.

Philosophy must begin *in medias res* (in the middle of things), in action itself, where there is an instinctive and arational belief in the natural world: "animal faith." For Santayana, animal faith is the arational basis for any knowledge claims. It is the nether world of biological order operating through our physical, non-conscious being generating beliefs that are "radically incapable of proof" (*Scepticism*, 35).

It is a vital constitutional necessity, to belief in discourse, in experience … . All these objects may conceivably be illusory. Belief in them however, is not grounded on a prior probability, but all judgements of probability are grounded on them. They express a rational instinct or instinctive reason, the waxing faith of an animal living in a world which he can observe and sometimes remodel (*Scepticism*, 308-309).

He describes these prejudices as "animal" in an effort to emphasize our biological base and community. This emphasis is similar to Wittgenstein's reference to convictions that are beyond being justified or unjustified as "something animal" (*On Certainty* 359). Ours is a long-standing primitive credulity, and our most basic beliefs are those of an animal creed: "that there is a world, that there is a future, that things sought can be found, and things seen can be eaten" (*Scepticism* 180).

Santayana (like Hume, Wittgenstein, and Strawson) holds there are certain inevitable beliefs; they are inescapable given nature and our individual physical history. And like Wittgenstein, he maintains that these beliefs are various and variable. They are determined by the interplay between environment and psyche, i.e., between our natural conditions and the inherited, physical "organisation of the animal" (the psyche). That we now inescapably believe in external objects and the general reliability of inductive reasoning, for example, is a result of physical history and the natural conditions of our world and ourselves. Since these beliefs are relative to our physical histories, if our history and biological order had been different, our natural beliefs would also be different.

The environment determines the occasions on which intuitions arise, the psyche -- the inherited organisation of the animal -- determines their form, and ancient conditions of life on earth no doubt determined which psyches should arise and prosper; and probably many forms of intuition, unthinkable to man, express the facts and the rhythms of nature to other animal minds (*Scepticism*, 88).

By displacing privileged mentalistic accounts with his pragmatic naturalism, Santayana challenges then prevailing structures in both American and English philosophies.

Santayana explicates the primary distinguishable characteristics of our knowledge in his four-book *Realms of Being*. Believing that philosophical terminology should have historical roots, Santayana employed classical terminology for these characteristics: matter, essence, spirit, and truth. And although these terms are central to many philosophical traditions, he views his work as "a revision of the categories of common sense, faithful in spirit to orthodox human tradition, and endeavouring only to clarify those categories and disentangle the confusions that inevitably arise … ." (*Realms* 826)

Within Santayana's naturalism, the origins of all events in the world are arbitrary, temporal, and contingent. Matter (by whatever name it is called) is the principle of existence. It is "often untoward, and an occasion of imperfection or conflict in things." (*Realm of Matter*, v) Hence, a "sour moralist" may consider it evil, but, according to Santayana, if one takes a wider view "matter would seem a good … because it is the principle of existence: it is all things in their potentiality and therefore the condition of all their excellence or possible perfection." (*Realm of Matter*, v) Matter is the non-discursive, natural foundation for all that is. In itself, it is neither good nor evil but may be perceived as such when viewed from the vested interest of animal life. Latent animal interests convert matter's non-discernible, neutral face to a smile or frown. But "moral values cannot preside over nature." (*Realm of Matter*, 134) Principled values are the products of natural forces: "The germination, definition, and prevalence of any good must be grounded in nature herself, not in human eloquence." (*Realm of Matter*, 131) From the point of view of origins, therefore, the realm of matter is the matrix and the source of everything: it is

nature, the sphere of genesis, the universal mother.

“Essence” is Santayana’s term for concepts and meanings. He draws on Aristotle’s notion of essence but removes all capacities for producing effects. An essence is a universal, an object of thought, not a material force. However, consciousness of an essence is generated by the interaction of a psyche and the material environment. Hence, matter remains as the origin of existence and the arena of action, and the realm of essence encompasses all possible thought.

“Truth,” if some disinterested observer could ascertain it, would constitute all the essences that genuinely characterize the natural world and all activities within it. Since all living beings have natural interests and preferences, no such knowledge of truth can exist. All conscious beings must ascertain belief about truth based on the success of actions that sustain life and permit periods of delight and joy.

Santayana uses the term “spirit” to mean consciousness or awareness. As early as 19 April 1909, Santayana wrote to his sister that he was writing a brand new system of philosophy to be called “The realms of Being” -- not the mineral vegetable and animal, but something far more metaphysical, namely Essence, Matter, and Consciousness. It will not be a long book, but very technical.” When the book was published in the 1930s, he had added his notion of truth and substituted “spirit” for “consciousness.” From his perspective, the substitution did not alter the meaning of consciousness but rather captured an entire tradition of philosophical and religious inquiry as well as borrowed associated ideas from eastern religions. But to the consternation of traditional views, many found the identity of spirit with consciousness a troublesome idea. And so they should, for with this identity Santayana removes the spiritual from the field of agency as well as from an alternative lifestyle. Following the tracks of Aristotle, he makes the spiritual life one form of culminating experiences arising from fulfilling activity.

Awareness evolved through the natural development of the physical world, and he demurs to scientific accounts for explanations of that development. Almost poetically, he sees spirit as emerging in moments of harmony between the psyche and the environment. Such harmony is temporary, and the disorganized natural forces permit spirit to arise "only spasmodically, to suffer and to fail. For just as the birth of spirit is joyous, because some nascent harmony evokes it, so the rending or smothering of that harmony, if not sudden, imposes useless struggles and suffering (*Birth of Reason,*53)." Accepting the world’s insecure equilibrium enables one to celebrate the birth of spirit. Reasoning, particularly reasoning associated with action, is a signal of the nascent activities of the psyche working to harmonize its actions with the environment, and if successful, reason permits individual and social organization to prosper while spirit leads to the delight of imagination and artistry.

Some commentators characterize Santayana as an epiphenomenalist, and there are some commonalities, specifically the view that spirit is not efficacious. But there also are considerable differences. Santayana does not characterize his view as one-way interactionism, primarily because he does not think of spirit as an object to be acted upon. Spirit is rather a distinguishable aspect of thought, generated in activity, and may be viewed more as a relational property. Santayana sometimes speaks of spirit and essence as supervening on material events. But lacking the distinctions of contemporary philosophy, it is difficult to

characterize Santayana’s philosophy of mind accurately. His view of consciousness is more celebrational, as opposed to being a burden or eliciting action. Spirit is "precisely the voice of order in nature, the music, as full of light as of motion, of joy as of peace, that comes with an even partial and momentary perfection in some vital rhythm (*Birth of Reason*, 53).”

Santayana’s account of spirit and essence, may lead one to wonder how Santayana can be included as a pragmatist, and this classification is accurate only if one includes an extended notion of pragmatic naturalism. For Santayana, explanations of human life, including reason and spirit, lie within the sciences. The nature of truth simply is correspondence with what is, but since humans, nor any other conscious being, are able to see beyond the determinant limits of their nature and environment, pragmatism becomes the test of truth rather than correspondence. In short, the nature of truth is correspondence while the test of truth is pragmatic. If an explanation continues to bear fruit over the long run, then it is accepted as truth until it is replaced by a better explanation. In this, Santayana’s account of pragmatic truth is more closely aligned with Peirce’s conception than that of James or Dewey, including a tripartite account of knowledge consisting of the subject, symbol, and object. Pragmatism properly is focused on scientific inquiry and explanations, and it is severely limited, even useless, in spiritual and aesthetic matters. Pragmatism is rooted in animal life, the need to know the world in a way that fosters successful action. If all life were constituted only by successful or unsuccessful activities, one’s fated circumstances would govern. But consciousness makes liberation possible and brings delight and festivity in material circumstances.

Santayana’s anti-foundationalism, non-reductive materialism, and pragmatic naturalism coupled with his emphasis on the spiritual life and his view of philosophy as literature anticipated many developments in philosophy and literary criticism that occurred in the latter half of the twentieth century, and these served as a challenge to the more humanistic naturalisms of John Dewey and other American naturalists. These views also provide the foundation for his view of ethics, political philosophy, and the spiritual life.

5. Ethics, Politics, and the Spiritual Life

Santayana’s moral philosophy is based on his naturalism. Most commentators classify Santayana as an extreme moral relativist who maintains that all individual moral perspectives have equal standing and are based on the heritable traits and environmental circumstances of individuals. This naturalistic approach applies to all living organisms. Nature does not establish a moral hierarchy of goods between animal populations nor between individual animals. However, this same moral relativism is also the basis for Santayana’s claim that the good of individual animals is clear and is subject to naturalistic or biological investigation.

Two tenets of his ethics are (1) the forms of the good are diverse, and (2) the good of each animal is definite and final. The moral terrain of animals, viewed from a neutral perspective, places all animal interests and goods as equal. Each good stems from heritable physical traits and is shaped by adaptations to the environment. Concluding that the “forms of the good are divergent,” Santayana holds that the good for each animal may differ, depending on the nature of the psyche and the circumstances, and may be

different for an individual animal in different times and environments. There is no one good for all, or even for an individual.

Seen as a whole, animal goods are not logically or morally ordered, that are natural, morally neutral forces. But no living being can observe all interests with such neutrality. Situated in a particular place and time with heritable traits, all living beings have interests originating from their physiology and physical environment. For Santayana, one may reasonably note that a neutral observer could view all moral perspectives as equal, but such a view must be balanced by the understanding that no animal stands on neutral ground. There is a polarity between the ideal neutral, objective understanding of behavior on the one hand and the committed and vested interest of particular living beings on the other hand. One may recognize that every animal good has its own standing, and one may respect that ideal, but "the right of alien natures to pursue their proper aims can never abolish our right to pursue ours."(*Persons and Places, 179)*

Santayana's second moral insight is that for each animal the good is definite and final. There are specific goods for each animal depending on the specific heritable traits and interests of the psyche and on the specific circumstances of the environment. Self-knowledge, then, is the distinguishing moral mark. The extent to which one knows one's interests, their complexity and centrality, will determine whether one can achieve a good life, provided the environment is accommodating. Santayana's philosophy rests on his naturalism and on his humane and sympathetic appreciation for the excellence of each life. But from the perspective of autobiography, Santayana's clear notion of self-knowledge, in the sense of the Greeks, is his most distinguishing mark. For Santayana, "integrity or self-definition is and remains first and fundamental in morals … ."(*Persons and Places* 170)

Self-knowledge requires a critical appreciation of one's culture and physical inheritance, and the ability to shape one's life in streams of conflicting goods within oneself and within one's community. Although this position is common to many considerations of political philosophy, Santayana's approach to politics was much more conservative than that normally associated with the founders of American pragmatism, such as James and Dewey.

Santayana's political conservatism is founded on his naturalism and his emphasis on self-realization and spirituality. He is concerned that liberal democracy may not provide a consistent basis for individual freedom and spirituality. The twin fears of private anarchy and public uniformity are the grounds for his criticisms of democracy, and his account of social justice focuses on the individual rather than the society. Santayana's inattentiveness to social inequality is perhaps understandable in the context of his naturalism where the final cause is the "authority of things." His basic contention that individual suffering is the worse feature of human life, not social inequality, causes him to focus more on the natural dilemmas of the individual rather than on social action. Coupling this argument with the view that all institutions, including governments, are inextricably rooted in their culture and background perhaps makes it understandable that he would not readily see how particular views of social inequality could be transferred readily from one culture to another. In addition, Santayana's European and particularly Spanish background influenced his attitudes toward social action. His repeated "Latin" perspective caused him to look with considerable suspicion toward forcing Anglo-Saxon outlooks on other cultures.

Yet, in individual matters he was remarkably forthcoming as when he provided financial support to numerous friends, often of quite different philosophical, literary, and political persuasions than his own.

Within the natural order every living entity stands on the same natural ground bathing equally in the impartial light of nature. No one can claim a central place above others. But each entity also has an embodied set of values, and the art of life is to structure one's environment in such a fashion as to best realize those embodied values, i.e., to place in harmony the natural forces of one's life and one's environment.

American democracy has an exacting challenge. Lacking the time to live in the mind, Americans use quantity as a justification for lack of quality in their achievements. Quantity is potentially infinite and assures unrivaled busy-ness, but is it worth it? No, according to Santayana, if self-realization is the goal of individual life. Of course, circumstances make it difficult, perhaps impossible, for some individuals to order their lives reasonably and attain the practical wisdom to achieve individual happiness. America's economic success would appear to make this possible for many, but to succeed Americans must abandon servility to mechanism and economics. What is needed is a life made free by a recovery of the capacity to have a vision of the good life (*Persons and Places*, xxxiv). According to Santayana, the fanatic is a person who has lost sight of their goals and redoubled their efforts. To supplant this busy, blind, relentlessly quantitative existence, we must regain sight of our goals. Individual life should be structured in light of those goals.

Santayana's focus is on the individual, and the role of the state is to protect and to enable the individual to flourish. The goal is not something far off to be worked toward. It is not a task to be accomplished and then supplanted by another task, as it thought much of American enterprise does. Rather it is the celebration of life in its festivities. It is Aristotle's practical wisdom: structuring individual life as it is, living it joyfully, and assuring that one's commitments are conducive to the delights of the intellect and consistent with the demands of the time and tradition. It is the exercise of one's free choice, shaping one's life through material well-being, but doing so to appreciate the poetic, dramatic quality of our own existence. To rush through life and die without the joy of living, that is the tragedy of American life.

For some, though perhaps not for many, the spiritual life will be an organizing good. The cultural background for the spiritual life is the religious life, primarily as found within the Catholic Church and informed by the late nineteenth century and early twentieth century accounts of eastern religions. But Santayana is not interested in an historical or doctrinal explication of the elements of traditional religion, rather the philosophical task is to discern the elements giving rise to such traditional views, and, in his own case, to explicate the aspects of these origins without the dogmatism of traditional religious belief.

Introducing the concept of a spiritual life, led some to see an inherent conflict between Santayana's life of reason and the spiritual life. In a letter to Milton Karl Munitz (23 July 1939), Santayana explains the different perspectives of the life of reason and the spiritual life:

I admit gladly that religion (= the "Spiritual life") is a natural interest, to be collated within the life of

reason with every other interest; but it is an interest in the ultimate, an adjustment to life, death, science, and politics; and though cultivated specially by certain minds at certain hours, it has no moral or natural claim to predominance. The races and ages in which it is absent will inevitably regard it as unnecessary and obstructive, because they tend to arrange their moral economy without religion at all. Those to whom religion is absorbing (e.g. the Indians) will on the contrary think a moral economy inferior in which no place and no influence is given to the monition of ultimate facts. I think you would not find my two voices inharmonious (I agree that they are different in pitch) if you did not live in America in the XXth century when the "dominance of the foreground" is so pronounced. The dominance of the distance or background would impose a different synthesis.

If the spiritual life was considered a dominating or guiding influence in structuring one's life, the way Santayana views reason, then one would be forced to choose between the life of reason and the life of the spirit as a monk or a nun much choose between the life of the world and that of the religious order. But for Santayana, no such conflict exists; spirituality is not choosing a way of living over an extended period of time. Indeed, any effort to choose such a life would be short lived, since the spiritual life is a life of receptivity to all that comes in the moment while suspending animal interests. Suspending one's specific natural interests, such as eating or sleeping, for any extended period would be both detrimental and tragic.

Consciousness essentially is only awareness, an attention to what is given, rather than being an instrument in reshaping the world. Consciousness, emerging late in the evolutionary pathway, is a flowering of happy circumstances that celebrates what is given, and when truly recognized, does only that. It is joyful, delighting in what is presented, and not troubled by where it leads or what it means. The more dower, moralistic, and evangelical aspects of religion he saw as confused efforts to make religion a science, a social club, or a political movement. Spirit, or consciousness, is momentary, fleeting, and depends on the physical forces of our bodies and environment in order to exist. Shaping one's life to enhance these spiritual, fleeting moments, extending them as long as is practical, is one of the delights of living for some people, but it is certainly not a goal for all, nor should it be.

Formal Learning Theory

Formal learning theory is the mathematical embodiment of a normative epistemology. It deals with the question of how an agent should use observations about her environment to arrive at correct and informative conclusions. Philosophers such as Putnam, Glymour and Kelly have developed learning theory as a normative framework for scientific reasoning and inductive inference.

Terminology. Cognitive science and related fields typically use the term "learning" for the process of gaining information through observation - hence the name "learning theory". To most cognitive scientists, the term "learning theory" suggests the empirical study of human and animal learning stemming from the behaviourist paradigm in psychology. The epithet "formal" distinguishes the subject of this entry from behaviourist learning theory. Because many developments in, and applications of, formal learning theory come from computer science, the term "computational learning theory" is also common. Philosophical terms for learning-theoretic epistemology include "logical reliability" (Kelly [1996], Glymour [1991]) and "means-ends epistemology" (Schulte [1999a]).

This entry focuses on the philosophical ideas and insights behind learning theory. It eschews theorems and definitions in favour of examples and informal arguments. Those interested in the mathematical substance of learning theory will find some references in the Bibliography, and a summary of the basic definitions in the Supplementary Document.

Philosophical characteristics. We can categorize normative epistemologies according to two criteria: (1) what are the objects of normative evaluation, and (2) what are the evaluation criteria to be employed? In learning theory, the basic object of normative evaluation is an inquirer's disposition to form beliefs given some evidence. The normative question that drives the theory is whether a given doxastic disposition serves the goals of inquiry or not. Most of learning theory examines which investigative strategies reliably lead to correct beliefs about the world.

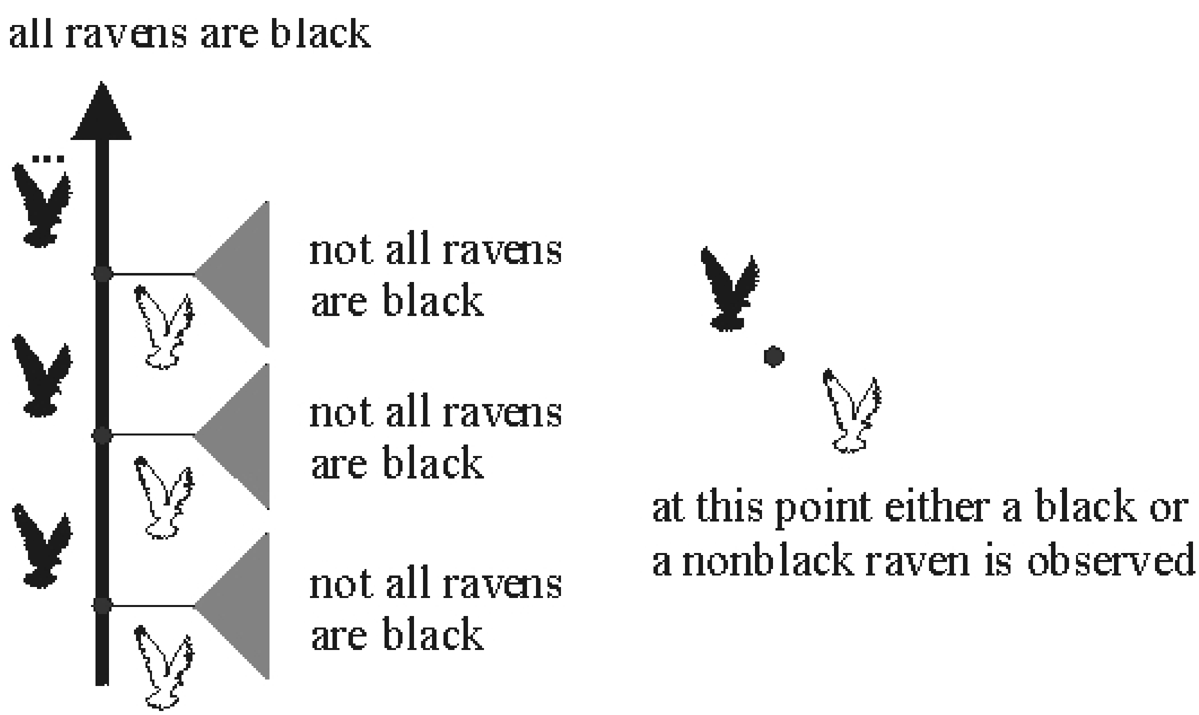
Overview. A number of examples will illustrate how means-ends analysis can lead us to endorse some ways of drawing inductive inferences and to reject others. Then I outline some of the general insights that lie behind such examples. Finally I relate means-ends epistemology to some other traditions in inductive epistemology.

1. Some Basic Examples

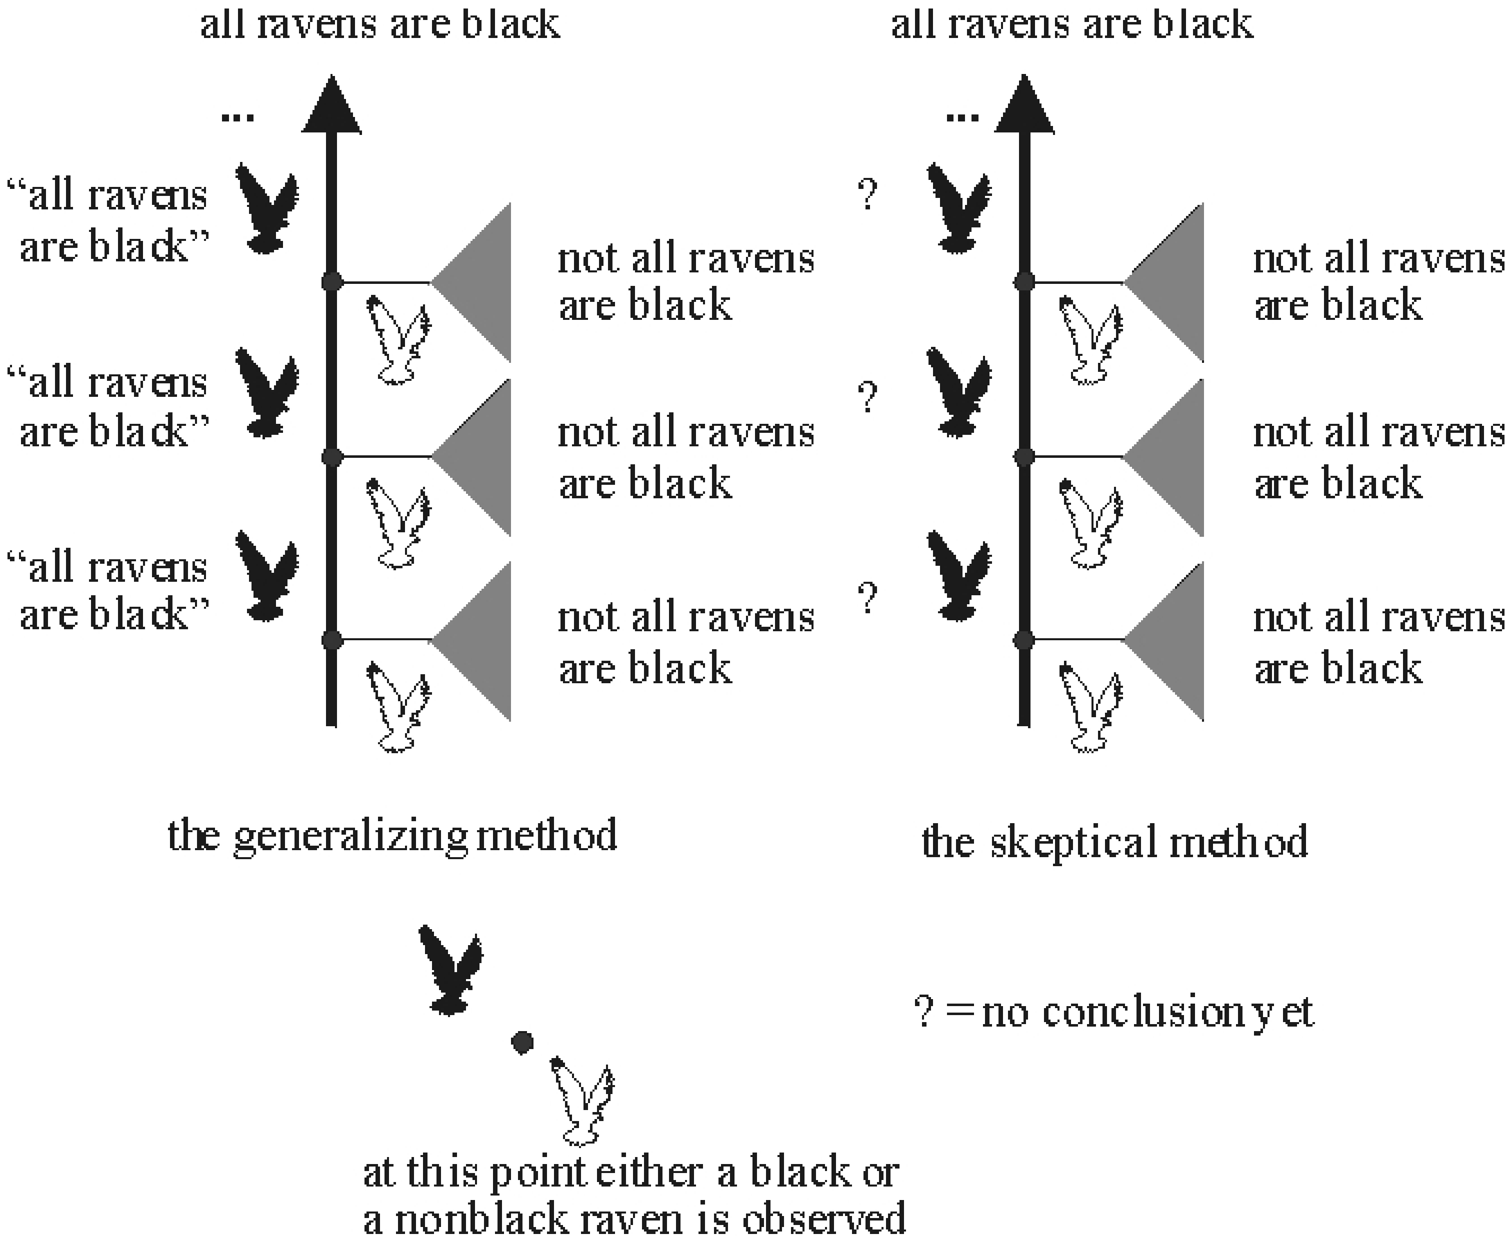
Learning-theoretic analysis assesses doxastic dispositions. Several terms for doxastic dispositions are in common use in philosophy; I will use "inductive strategy", "inference method" and most frequently "inductive method" to mean the same thing. The best way to understand how learning theory evaluates inductive methods is to work through some examples. The following presentation begins with some very simple inductive problems and moves on to more complicated -- and more realistic -- settings.

Universal Generalization

Let’s revisit the classic question of whether all ravens are black. Imagine an ornithologist who tackles this problem by examining one raven after another. There is exactly one observation sequence in which only black ravens are found; all others feature at least one nonblack raven. The figure below illustrates the possible observation sequences. Dots in the figure denote points at which an observation may be made. A black bird to the right of a dot indicates that at this stage, a black raven is observed; similarly for a white bird to the left of a dot. Given a complete sequence of observations, either all observed ravens are black or not; the figure labels complete observation sequences with the statement that is true of them. The gray fan indicates that after the observation of a white raven, the claim that not all ravens are black holds on all observation sequences resulting from further observations.



If the world is such that only black ravens are found, we would like the ornithologist to settle on this generalization. (It may be possible that some nonblack ravens remain forever hidden from sight, but even then the generalization "all ravens are black" at least gets the observations right.) If the world is such that eventually a nonblack raven is found, then we would like the ornithologist to arrive at the conclusion that not all ravens are black. This specifies a set of goals of inquiry. For any given inductive method that might represent the ornithologist’s disposition to adopt conjectures in the light of the evidence, we can ask whether that method measures up to these goals or not. There are infinitely many possible methods to consider; we’ll look at just two, a sceptical one and one that boldly generalizes. The bold method conjectures that all ravens are black after seeing that the first raven is black. It hangs on to this conjecture unless some nonblack raven appears. The sceptical method does not go beyond what is entailed by the evidence. So if a nonblack raven is found, the skeptical method concludes that not all ravens are black, but otherwise the method does not make a conjecture one way or another. The figure below illustrates both the generalizing and the sceptical method.



Do these methods attain the goals we set out? Consider the bold method. There are two possibilities: either all observed ravens are black, or some nonblack raven is found. In the first case, the method conjectures that all ravens are black and *never abandons this conjecture*. In the second case, the method concludes that not all ravens are black as soon as the first nonblack raven is found. Hence *no matter how* the evidence comes in, eventually the method gives the right answer as to whether all ravens are black and *sticks* with this answer. Learning theorists call such methods *reliable* because they settle on the right answer no matter what observations the world provides.

The skeptical method does not measure up so well. If a nonblack raven appears, then the method does arrive at the correct conclusion that not all ravens are black. But if all ravens are black, the skeptic never takes an "inductive leap" to adopt this generalization. So in that case, the skeptic fails to provide the right answer to the question of whether all ravens are black.

This illustrates how means-ends analysis can evaluate methods: the bold method meets the goal of reliably arriving at the right answer, whereas the skeptical method does not. Note the character of this argument against the skeptic: The problem, in this view, is not that the skeptic violates some canon of rationality, or fails to appreciate the "uniformity of nature". The learning-theoretic analysis concedes to the skeptic that no matter how many black ravens have been observed in the past, the next one could be white. The issue is that if all observed ravens are indeed black, then the skeptic *never answers* the question "are all ravens black?". Getting the right answer to that question requires generalizing from the evidence *even though* the

generalization could be wrong.

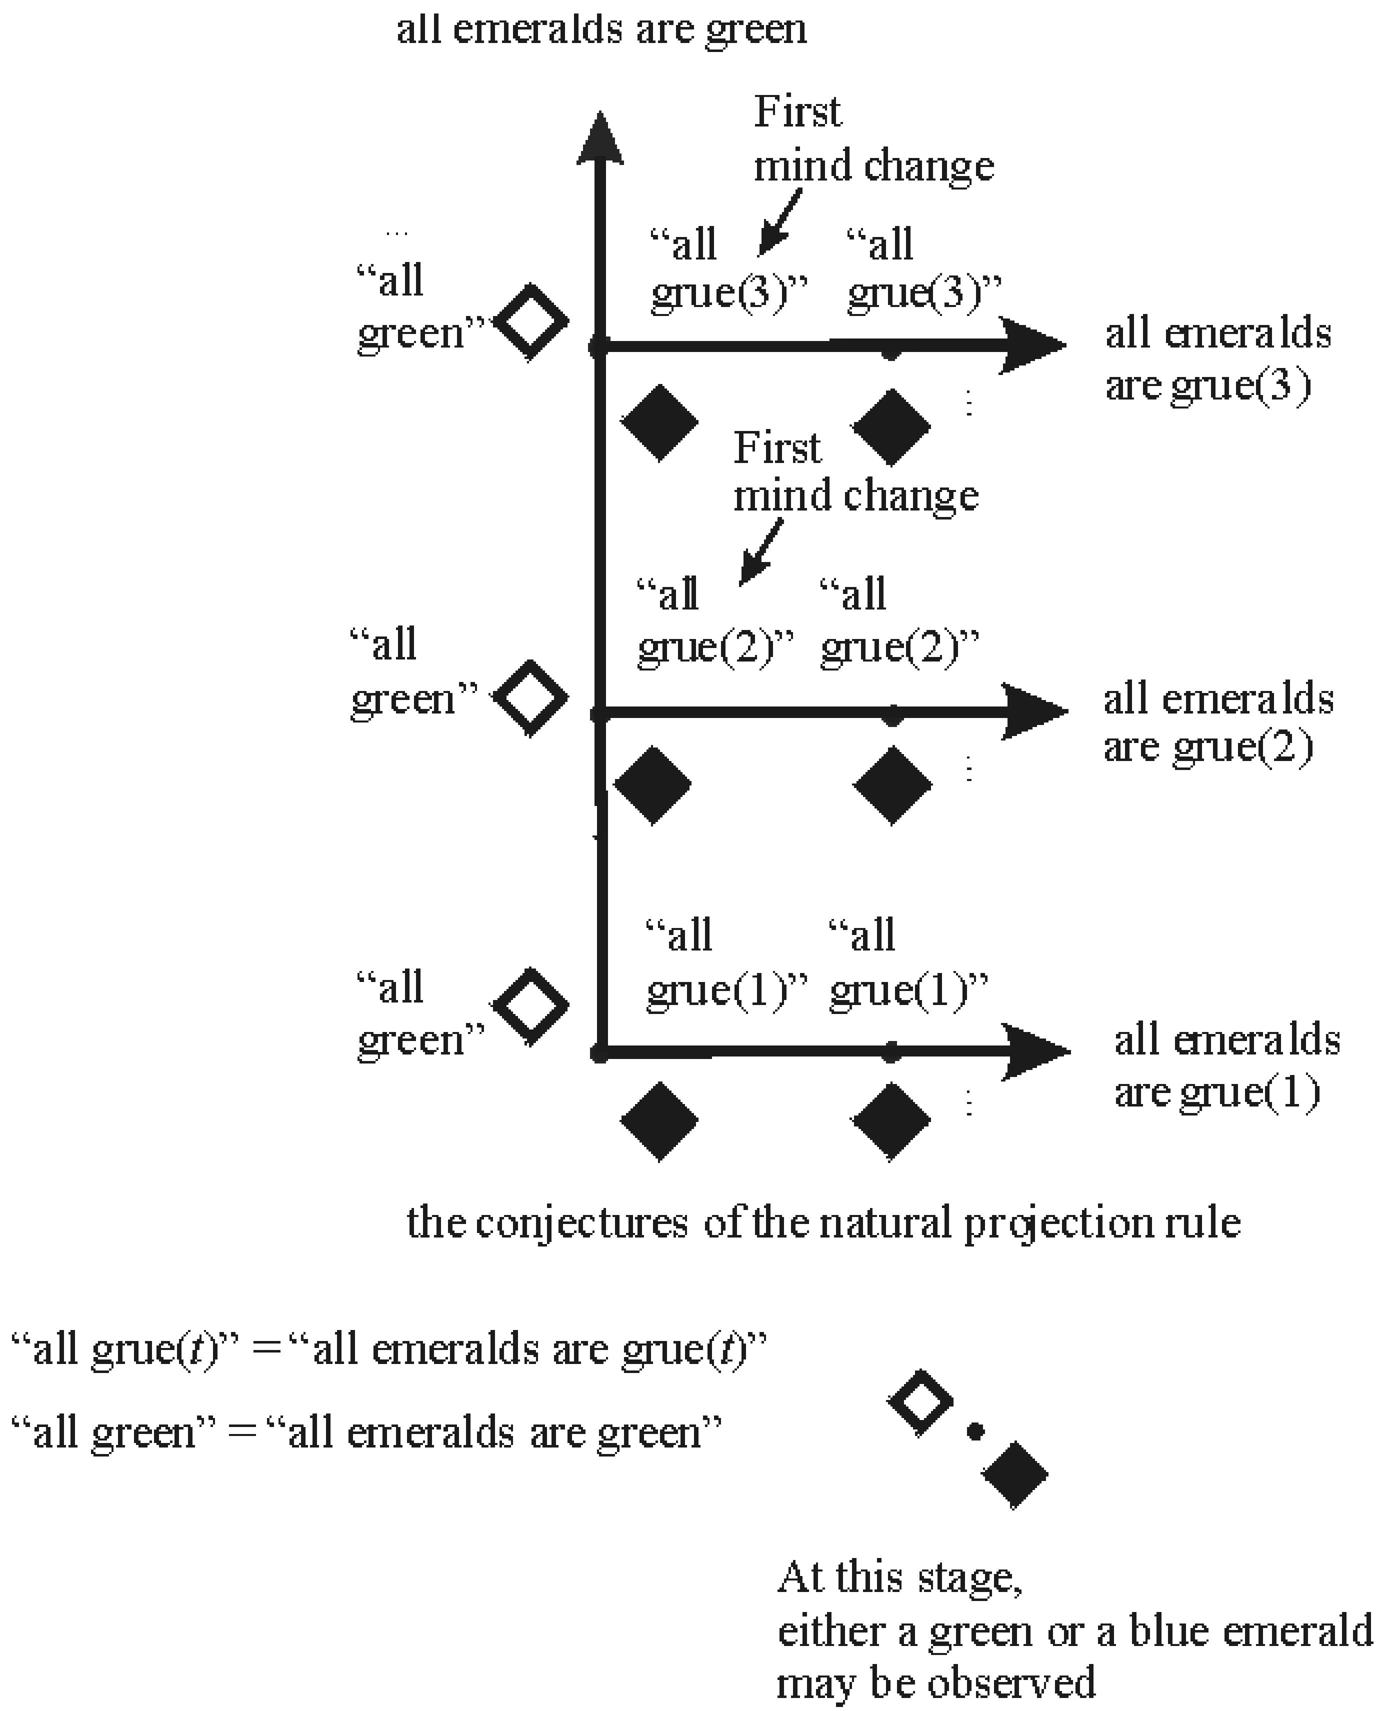
As for the bold method, it’s important to be clear on what it does and does not achieve. The method will eventually settle on the right answer -- but it (or we) may never *be certain* that it has done so. As William James put it, "no bell tolls" when science has found the right answer. We are certain that the method will eventually settle on the right answer; but we may never be certain that the current answer is the right one. This is a subtle point. The next example illustrates this point further.

A Riddle of Induction

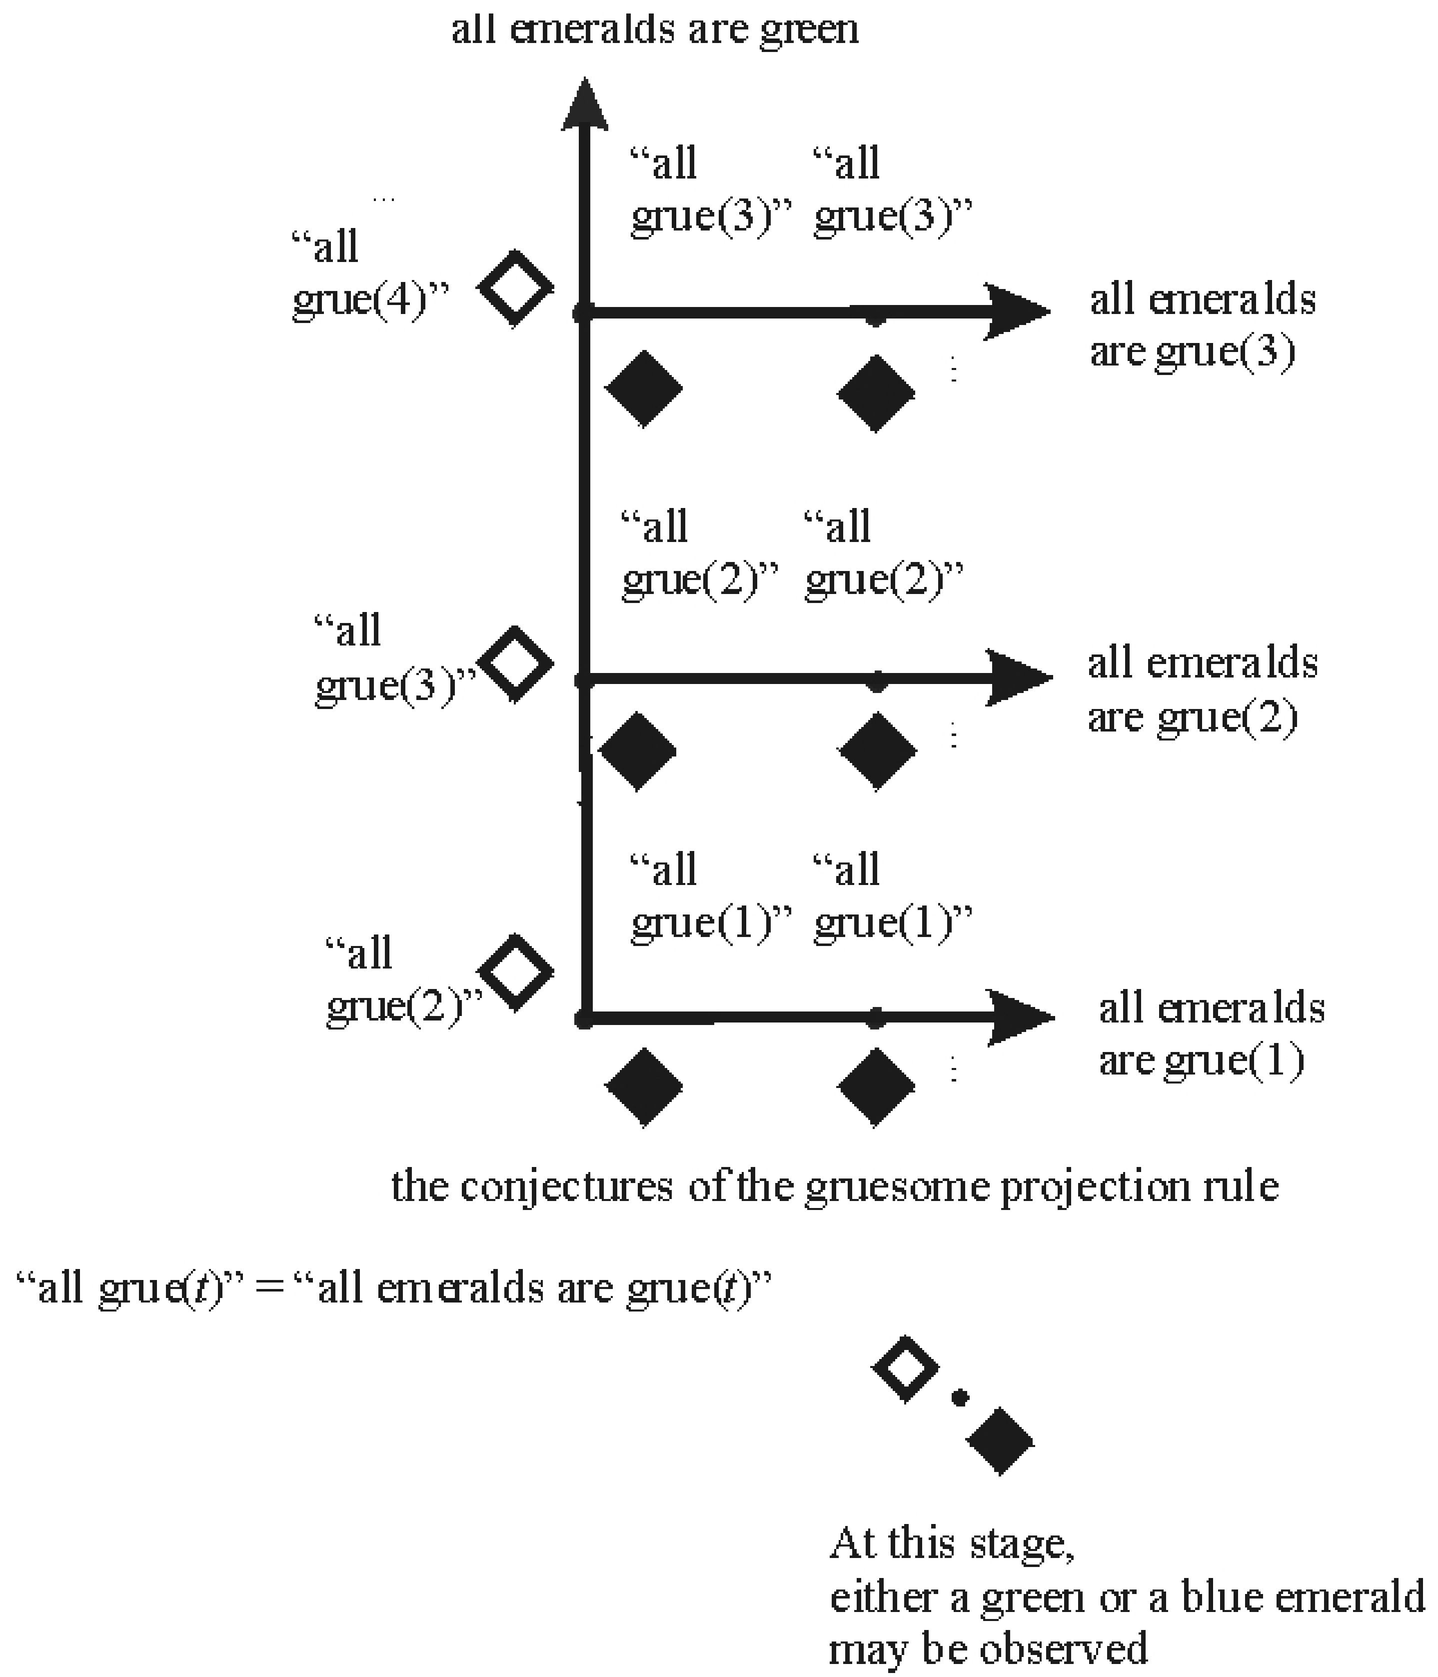
Nelson Goodman posed a famous puzzle about inductive inference known as the (New) Riddle of Induction ([Goodman 1983]). Our next example is inspired by his puzzle. Goodman considered generalizations about emeralds, involving the familiar colours of green and blue, as well as certain unusual ones:

> Suppose that all emeralds examined before a certain time *t* are green ... Our evidence statements assert that emerald *a* is green, that emerald *b* is green, and so on...
>
> Now let us introduce another predicate less familiar than "green’’. It is the predicate "grue’’ and it applies to all things examined before *t* just in case they are green but to other things just in case they are blue. Then at time *t* we have, for each evidence statement asserting that a given emerald is green, a parallel evidence statement asserting that emerald is grue.
>
> The question is whether we should conjecture that all emeralds are green rather than that all emeralds are grue when we obtain a sample of green emeralds examined before time *t*, and if so, why.

Clearly we have a family of grue predicates in this problem, corresponding to different "critical times" *t*; let’s write grue(*t*) to denote these. Following Goodman, let us refer to methods as projection rules in discussing this example. A projection rule succeeds in a world just in case it settles on a generalization that is correct in that world. Thus in a world in which all examined emeralds are found to be green, we want our projection rule to converge to the proposition that all emeralds are green. If all examined emeralds are grue(*t*), we want our projection rule to converge to the proposition that all emeralds are grue(*t*). Note that this stipulation treats green and grue predicates completely on a par, with no bias towards either. As before, let us consider two rules: the "natural" projection rule which conjectures that all emeralds are green as long as only green emeralds are found, and the "gruesome" rule which keeps projecting the next grue predicate consistent with the available evidence. Expressed in the green-blue vocabulary, the gruesome projection rule conjectures that after observing some number of *n* green emeralds, all future ones will be blue. The figure below illustrates the possible observation sequences and the natural projection rule in this model of the New Riddle of Induction.



The following figure shows the gruesome projection rule.



How do these rules measure up to the goal of arriving at a true generalization? Suppose for the sake of the example that the only serious possibilities under consideration are that either all emeralds are green or that all emeralds are grue(t) for some critical time t. Then the natural projection rule settles on the correct generalization no matter what the correct generalization is. For if all emeralds are green, the natural projection rule asserts this fact from the beginning. And suppose that all emeralds are grue(t) for some critical time t. Then at time t, a blue emerald will be observed. At this point the natural projection rule settles on the conjecture that all emeralds are grue(t), which must be correct given our assumption about the possible

observation sequences. Thus no matter what evidence is obtained in the course of inquiry -- consistent with our background assumptions -- the natural projection rule eventually settles on a correct generalization about the colour of emeralds.

The gruesome rule does not do as well. For if all emeralds are green, the rule will never conjecture this fact because it keeps projecting grue predicates. Hence there is a possible observation sequence -- namely those on which all emeralds are green -- on which the gruesome rule fails to converge to the right generalization. So means-ends analysis would recommend the natural projection rule over the gruesome rule. Some comments are in order.

1. As in the previous example, nothing in this argument hinges on arguments to the effect that certain possibilities are not to be taken seriously a priori. In particular, nothing in the argument says that generalizations with grue predicates are ill-formed, unlawlike, or in some other way a priori inferior to "all emeralds are green".

2. The analysis does not depend on the vocabulary in which the evidence and generalizations are framed. For ease of exposition, I have mostly used the green-blue reference frame. However, grue-bleen speakers would agree that the aim of reliably settling on a correct generalization requires the natural projection rule rather than the gruesome one, even if they would want to express the conjectures of the natural rule in their grue-bleen language rather than the blue-green language that we have used so far. (For more on the language-invariance of means-ends analysis see Section 4 (The Limits of Inquiry and the Complexity of Empirical Problems), as well as Schulte [1999a, 1999b]).

3. Though the analysis does not depend on language, it does depend on assumptions about what the possible observation sequences are. The example as described above seems to comprise the possibilities that correspond to the colour predicates Goodman himself discussed. But means-ends analysis applies just as much to other sets of possible predicates. Schulte [1999a, 1999b] and Chart [2000] discuss a number of other versions of the Riddle of Induction, in some of which means-ends analysis favours projecting that all emeralds are grue on a sample of all green emeralds.

4. Even with the assumptions granted so far, there are reliable projection rules that project that all emeralds are grue(t) on a sample of all green emeralds. For example, the projection rule "conjecture that all emeralds are grue(3) until 3 green emeralds are observed; then conjecture that all emeralds are green until a blue emerald is observed" is guaranteed to eventually settle on a correct generalization just like the natural projection rule. (It’s a worthwhile exercise to verify the reliability of this rule.) I will discuss criteria for further restricting the space of rules in Section 3 (The Long Run in The Short Run).

Generalizations with Exceptions

Let’s return to the world of ravens. This time the ornithological community is more guarded in its generalizations concerning the colour of ravens. Two competing hypotheses are under investigation: (1) That basically all ravens are black, but there may be a finite number of exceptions to that rule, and (2) that basically all ravens are white, but there may be a finite number of exceptions to that rule. Assuming that one or the other of these hypotheses is correct, is there an inductive method that reliably settles on the right one? What makes this problem more difficult than our first two is that each hypothesis under investigation is consistent with any finite amount of evidence. If 100 white ravens and 50 black ravens are found, either the 50 black ravens or the 100 white ravens may be the exception to the rule. In terminology made familiar by Karl Popper’s work, we may say that neither hypothesis is falsifiable. As a consequence, the inductive strategy from the previous two examples will not work here. This strategy was basically to adopt a "bold" universal generalization, such as "all ravens are black" or "all emeralds are green", and to hang on to this conjecture as long as it "passes muster". However, when rules with possible exceptions are under investigation, this strategy is unreliable. For example, suppose that an inquirer first adopts the hypothesis that "all but finitely many ravens are white". It may be the case that from then on, only black ravens are found. But each of these apparent counterinstances can be "explained away" as an exception. If the inquirer follows the principle of hanging on to her conjecture until the evidence is logically inconsistent with the conjecture, she will never abandon her false belief that all but finitely many ravens are white, much less arrive at the correct belief that all but finitely many ravens are black.

Reliable inquiry requires a more subtle investigative strategy. Here is one (of many). Begin inquiry with either competing hypothesis, say "all but finitely many ravens are black". Choose some cut-off ratio to represent a "clear majority"; for definiteness, let's say 70%. If the current conjecture is that all but finitely many ravens are black, change your mind to conjecture that all but finitely many ravens are white just in case over 70% of observed ravens are in fact white. Proceed likewise if the current conjecture is that all but finitely many ravens are white when over 70% of observed ravens are in fact black.

A bit of thought shows that this rule reliably identifies the correct hypothesis in the long run, no matter which of the two competing hypotheses is correct. For if all but finitely many ravens are black, eventually the nonblack exceptions to the rule will be exhausted, and an arbitrarily large majority of observed ravens will be black. Similarly if all but finitely many ravens are white.

The way in which this reliable method is sensitive to the frequency of occurrences of black resp. white ravens is reminiscent of statistical methods. This suggests considering statistical generalizations such as "the percentage of white ravens in the total population of ravens is 20%". Hans Reichenbach held that the central aim of inductive inference were generalizations of precisely that sort. More generally, we may consider hypotheses about proportions such as "the proportion of white ravens is between 10% and 20%". Kelly examines in detail various hypotheses of this kind and establishes when there are reliable methods for testing them. He also provides a learning-theoretic interpretation of classical statistical tests of a parameter for a probability distribution [Kelly 1996, Ch.3.4].

Generalizations with exceptions illustrate some subtle nuances in the relationship between Popperian falsificationism and the learning-theoretic idea of reliable convergence to the truth. In some settings of inquiry, notably those involving universal generalizations, a naively Popperian "conjectures-and-refutations" approach of hanging on to conjectures until the evidence falsifies them does yield a reliable inductive method. In other problems, like the current example, it does not. Generally speaking problems with unfalsifiable hypotheses require something other than the conjectures-and-refutations recipe for reliable methods (this assertion hinges on what exactly one means by "falsifiable hypothesis"; see Section 4 (The Limits of Inquiry and the Complexity of Empirical Problems) as well as [Schulte and Juhl 1996]). A Popperian might respond that such hypotheses are "unscientific" and hence it is no concern that the conjectures-and-refutations approach fails to reliably identify a correct hypothesis when unfalsifiable hypotheses are involved. But intuitively, a claim like "all but finitely many ravens are black" appears to be a respectable empirical hypothesis. More importantly than intuition, at least from the point of view of means-ends epistemology, it is possible to reliably assess the truth of such claims in the long run, even though all hypotheses under investigation are consistent with any finite amount of evidence. This constitutes a clear sense in which inquiry can test these hypotheses against empirical evidence in order to find the truth. If we allow that we would want inductive methodology to extend to problems like this one, the moral is that relying on falsifications is sometimes, but *not always*, the best way for inquiry to proceed.

2. Case Studies in Scientific Practice

This section provides further examples to illustrate learning-theoretic analysis. The examples in this section are more realistic and address methodological issues arising in scientific practice. The space constraints of the encyclopedia format allow only an outline of the full analysis; there are references to more detailed discussions below.

Conservation Laws in Particle Physics

One of the hallmarks of elementary particle physics is the discovery of new conservation laws that apply only in the subatomic realm [Ford 1963, Ne'eman and Kirsh 1983, Feynman 1965]. (Feynman groups one of them, the conservation of Baryon Number, with the other "great conservation laws" of energy, charge and momentum.) Simplifying somewhat, conservation principles serve to explain why certain processes involving elementary particles do not occur: the explanation is

that some conservation principle was violated (cf. Omnes [1971, Ch.2]). So a goal of particle inquiry is to find a set of conservation principles, such that for every process that is possible according to the (already known) laws of physics, there is some conservation principle that rules out that process. And if a process is in fact observed to occur, then it ought to satisfy all conservation laws that we have introduced.

This constitutes an inference problem to which we may apply means-ends analysis. An inference method produces a set of conservation principles in response to reports of observed processes. Means-ends analysis asks which methods are guaranteed to settle on conservation principles that account for all observations, that is, that rule out unobserved processes and allow observed processes. [Schulte 2000] describes an inductive method that accomplishes this goal. Interestingly, the conservation principles that this method would posit on the currently available evidence appear to be close to the ones that physicists have introduced.

It turns out that for some physical processes, the only way to get empirically adequate conservation principles is by positing that some hidden particles have gone undetected. It is remarkable that to find conservation principles that are consistent with what is observed, sometimes the only option is to form hypotheses about what is *un*observed. It is easy to miss this phenomenon without the scrutiny that means-ends analysis requires. Extending our problem so that inference methods not only posit conservation laws but also hidden particles makes inquiry more difficult. But if we grant the particle theorist the assumption that there are only finitely many types of hidden particles, then there is a still a method that is guaranteed to settle eventually on a theory that makes correct predictions about the observable phenomena, using a combination of conservation laws and hidden particles. A detailed discussion of the conservation law inference problem is in [Schulte 2000].

Models of Cognitive Architecture

Some philosophers of mind have argued that the mind is composed of fairly independent modules. Each module has its own "input" from other modules and sends "output" to other modules. For example, an "auditory analysis system" module might take as input a heard word and send a phonetic analysis to an “auditory input lexicon”. The idea of modular organization raises the empirical question of what mental modules there are and how they are linked to each other. A prominent tradition of research in cognitive neuroscience has attempted to develop a model of mental architecture along these lines by studying the responses of normal and abnormal subjects to various stimuli. The idea is to compare normal reactions with abnormal ones -- often caused by brain damage -- so as to draw inferences about which mental capacities depend on each other and how.

Glymour [1994] asked the reliabilist question whether there are inference methods that are guaranteed to eventually settle on a true theory of mental organization, given exhaustive evidence about normal and abnormal capacities and reactions. He argued that for some possible mental architectures, no amount of evidence of the stimulus-response kind can distinguish between them. Since the available evidence determines the conjectures of an inductive method, it follows that there is no guarantee that a method will settle on the true model of cognitive architecture.

In further discussion, Bub [1994] showed that if we grant certain restrictive assumptions about how mental modules are connected, then a complete set of behavioural observations would allow a neuropsychologist to ascertain the module structure of a (normal) mind. In fact, under Bub’s assumptions there is a reliable method for identifying the modular structure. Glymour has also explored to what extent richer kinds of evidence would resolve underdetermination of mental architecture by behavioural evidence. (One example of richer evidence are double disassocations. An example of a double dissocation would be a pair of patients, one who has a normal capacity for understanding spoken words, but fails to understand written ones, and another who understands written words but not spoken ones.)

Some more case studies of this sort may be found in [Kelly 1996, Ch. 7.7, Harell 2000]. The main interest of such studies lies of course in what they say about the particular domain under investigation. But they also illustrate some general features of learning theory:

1. *Generality*. The basic notions of the theory are very general. Essentially, the theory applies whenever one has a question that prompts inquiry, a number of candidate answers, and some evidence for deciding among the answers. Thus means-ends analysis can be applied in any discipline aimed at empirical knowledge, for example physics or psychology.

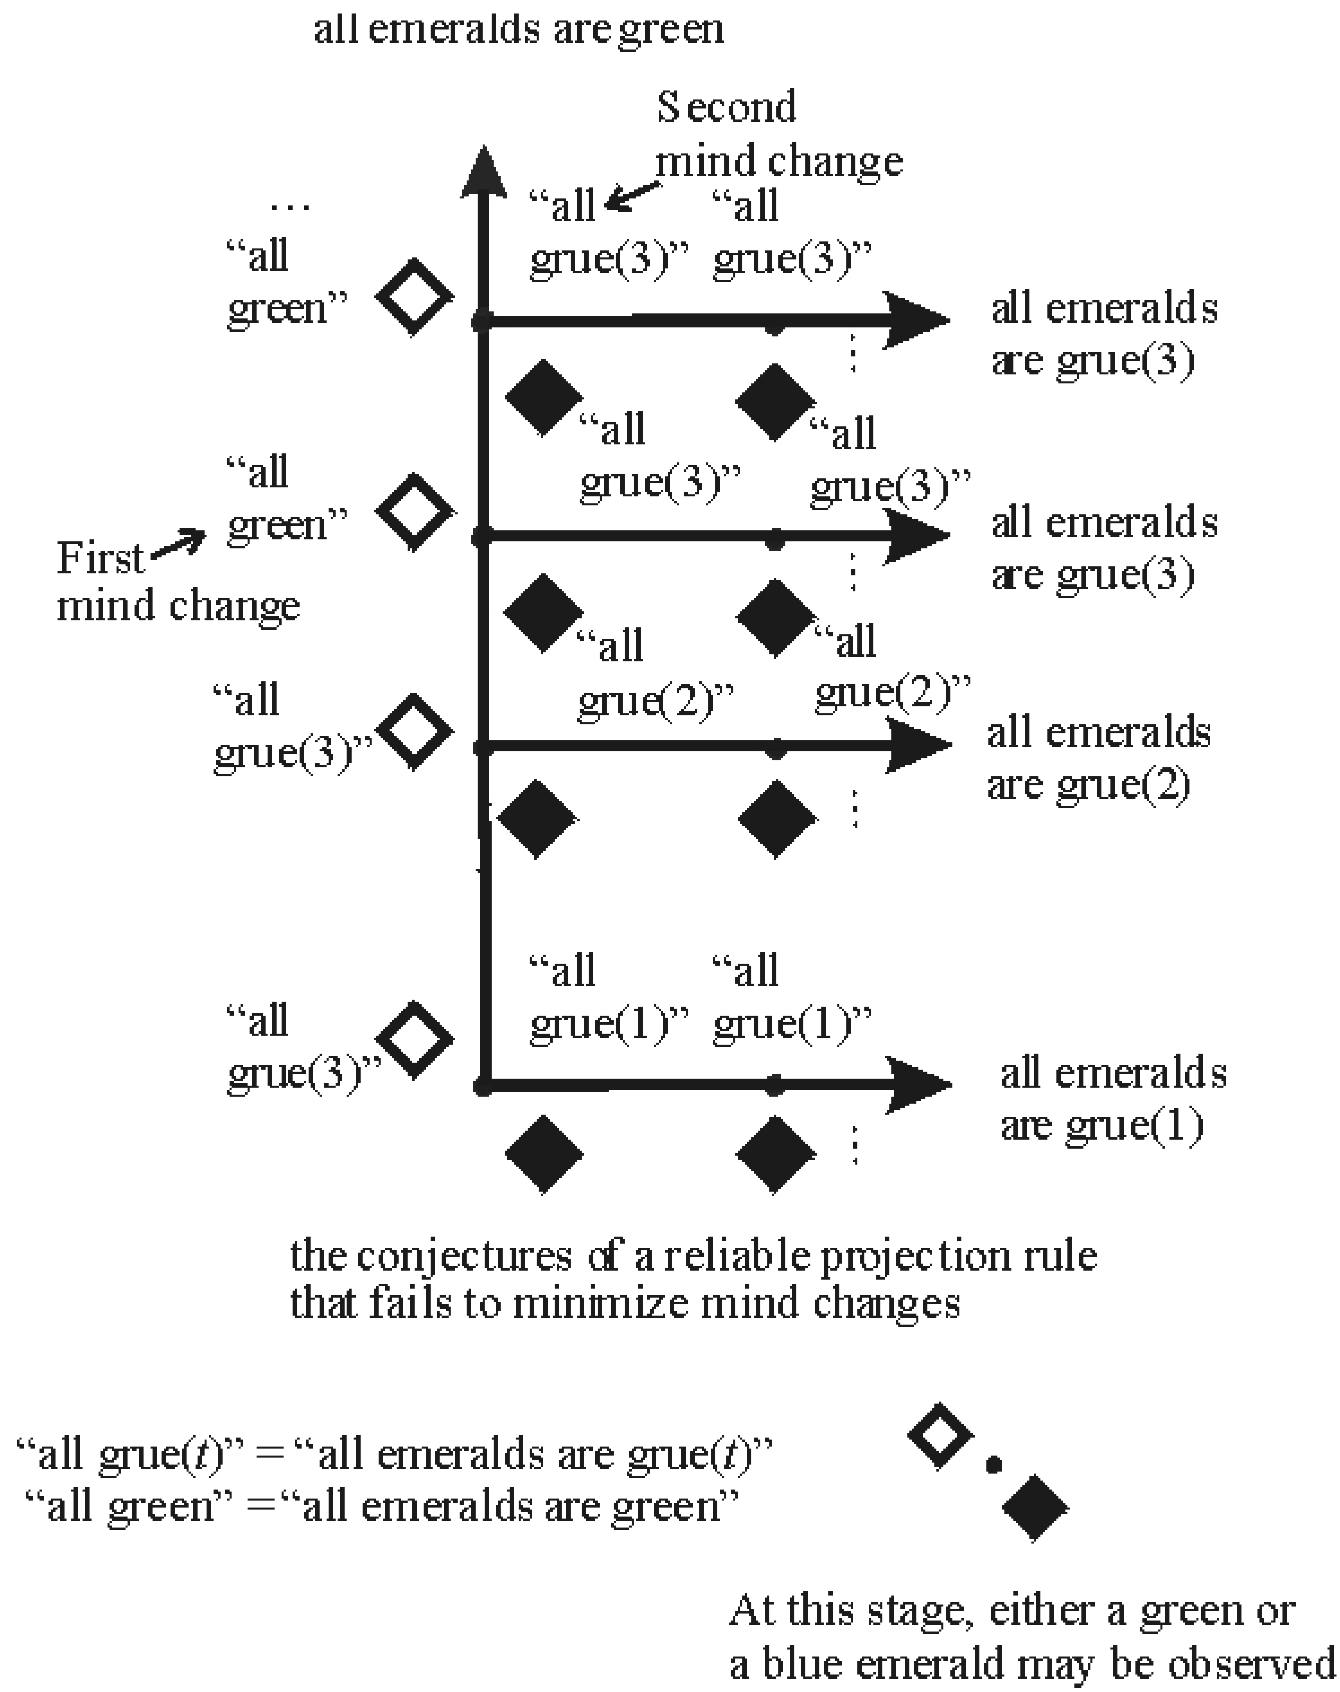
2. *Context Dependence*. Learning theory is pure normative a priori epistemology, in the sense that it deals with standards for assessing methods in possible settings of inquiry. But the approach does not aim for universal, context-free methodological maxims. The methodological recommendations depend on contingent factors, such as the operative methodological norms, the questions under investigation, the background assumptions that the agent brings to inquiry, the observational means at her disposal, her cognitive capacities, and her epistemic aims. As a consequence, to evaluate specific methods in a given domain, as in the case studies mentioned, one has to study the details of the case in question. The means-ends analysis often rewards this study by pointing out what the crucial methodological features of a given scientific enterprise are, and by explaining precisely why and how these features are connected to the success of the enterprise in attaining its epistemic aims.

3. *Trade-offs*. In the perspective of means-ends epistemology, inquiry involves an ongoing struggle with hard choices, rather than the execution of a universal "scientific method". The inquirer has to balance conflicting values, and may consider various strategies such as accepting difficulties in the short run hoping to resolve them in the long run. For example in the conservation law problem, there can be conflicts between theoretical parsimony, i.e., positing fewer conservation laws, and ontological parsimony, i.e., introducing fewer hidden particles. For another example, a particle theorist may accept positing undetected neutrinos in the hopes that they will eventually be observed as science progresses. An important learning-theoretic project is to examine when such tradeoffs arise and what the options for resolving them are. The next section deals with some aspects of this topic.

3. The Long Run in the Short Run

A longstanding criticism of convergence to the truth as an aim of inquiry is that, while fine in itself, this aim is consistent with any crazy behaviour in the short run [Salmon 1991]. For example, we saw in the New Riddle of Induction that a reliable projection rule can conjecture that the next emerald will be blue no matter how many green emeralds have been found -- as long as *eventually* the rule projects "all emeralds are green". One response is that if means-ends analysis takes into account other epistemic aims *in addition* to long-run convergence, then it *can* provide strong guidance for what to conjecture in the short run.

To illustrate this point, let us return to the Goodmanian Riddle of Induction. Since Plato, philosophers have considered the idea that *stable* true belief is better than unstable true belief, and epistemologists such as Sklar [1975] have advocated similar principles of "epistemic conservatism". Kuhn tells us that a major reason for conservatism in paradigm debates is the cost of changing scientific beliefs [Kuhn 1970]. In this spirit, learning theorists have examined methods that minimize the number of times that they change their theories before settling on their final conjecture. Such methods are said to minimize *mind changes*. The New Riddle of Induction turns out to be a nice illustration of this idea. Consider the natural projection rule (conjecture that all emeralds are green on a sample of green emeralds). If all emeralds are green, this rule never changes its conjecture. And if all emeralds are grue(*t*) for some critical time *t*, then the natural projection rule abandons its conjecture "all emeralds are green" at time *t* -- one mind change -- and thereafter correctly projects "all emeralds are grue(*t*)". Remarkably, rules that project grue rather than green do not do as well. For example, consider a rule that conjectures that all emeralds are grue(3) after observing one green emerald. If two more green emeralds are observed, the rule's conjecture is falsified and it must eventually change its mind, say to conjecture that all emeralds are green (suppose that green emeralds continue to be found). But then at that point, a blue emerald may appear, forcing a second mind change. This argument can be generalized to show that the aim of minimizing mind changes allows only the green predicate to be projected on a sample of all green emeralds [Schulte 1999a]. We saw in a figure above how the natural projection rule changes its mind at most once; the figure below illustrates in a typical case how an unnatural projection rule may have to change its mind twice or more.



The conservation law problem discussed in the previous section provides another illustration of how additional epistemic aims can lead to constraints in the short run. In this problem, reliability and minimizing mind changes require a particle theorist to adopt a conservation theory that rules out as many unobserved reactions as possible. In certain circumstances, the only way to attain this aim is to introduce hidden particles. Long-run reliability by itself may require that the theorist introduce hidden particles *eventually*; the additional goal of minimizing mind changes -- stable belief -- dictates exactly when this should occur [Schulte 2000].

Learning theorists have examined other epistemic aims, such as *fast convergence* to a right answer and *avoiding errors* before settling on the truth. Some of these desiderata come into conflict whereas others turn out to stand and fall together, often in surprising ways. For example, Kelly has shown that under very general circumstances, minimizing mind changes and minimizing errors vindicate the same inductive methods [Kelly 2001].

4. The Limits of Inquiry and the Complexity of Empirical Problems

After seeing a number of examples like the ones above, one begins to wonder what the pattern is. What is it about an empirical question that allows inquiry to reliably arrive at the correct answer? What general insights can we gain into how reliable methods go about testing hypotheses? Learning theorists answer these questions with *characterization theorems*. Characterization theorems are generally of the form “it is possible to attain this standard of empirical success in a given inductive problem if and only if the inductive problem meets the following conditions”. There are a number of standards of success in inquiry -- reliable convergence to the truth, fast reliable convergence, reliable convergence with few mind changes -- and hence correspondingly many characterization theorems.

A fundamental result describes the conditions under which a method can reliably find the correct hypothesis among a countably infinite or finite number H_1, H_2, …, H_n, …. of mutually exclusive hypotheses that jointly cover all possibilities consistent with the inquirer’s background assumptions. This is possible just in case each of the hypotheses is a countable disjunction of refutable empirical claims. By “refutable” I mean that if the claim is false, the evidence combined with the inquirer’s background assumptions will eventually conclusively falsify the hypothesis (see Schulte and Juhl [1996], Kelly [1996, Ch. 3.3]). For illustration, let’s return to the ornithological example with two alternative hypotheses: (1) all but finitely many swans are white, and (2) all but finitely many swans are black. As we saw, it is possible in the long run to reliably settle which of these two hypotheses is correct. Hence by the characterization theorem, each of the two hypotheses must be a disjunction of refutable empirical claims. To see that this indeed is so, observe that “all but finitely many swans are white” is logically equivalent to the disjunction

“at most 1 swan is black or at most 2 swans are black … or at most n swans are black … or…”,

and similarly for “all but finitely many swans are black”. Each of the claims in the disjunction is refutable, in the sense of being eventually falsified whenever it is false. For example, take the claim that “at most 3 swans are black”. If this is false, more than 3 black swans will be found, at which point the claim is conclusively falsified.

A few points will help explain the significance of characterization theorems like this one.

1. *Structure of Reliable Methods*. Characterization theorems tell us how the structure of reliable methods corresponds to the structure of the hypotheses under investigation. For example, the theorem mentioned establishes a connection between falsifiability and testability, but one that is more attenuated than the naïve Popperian envisions: it is not necessary that the hypotheses under test be directly falsifiable; rather, there must be ways of strengthening each hypothesis that yield a countable number of refutable “subhypotheses”. We can think of these refutable subhypotheses as different ways in which the main hypothesis may be true. (For example, one way in which "all but finitely many ravens are white" is true is if there are are at most 10 black ravens,; another if there are at most 100 black ravens, etc.)

2. *Import of Background Assumptions.* The characterization result draws a line between the solvable and unsolvable problems. Background knowledge reduces the inductive complexity of a problem; with enough background knowledge, the problem crosses the threshold between the unsolvable and the solvable. In many domains of empirical inquiry, the pivotal background assumptions are those that make reliable inquiry feasible. (Kuhn [1970] makes similar points). For example, in the particle dynamics problem, it is the assumption that some set of linear conservation laws is empirically adequate that

permits us to reliably find an empirically adequate theory of particle reactions. It seems that, conversely, in domains in which the available background assumptions do not reduce the complexity of the empirical problems enough, there is a sense that inquiry is not sufficiently constrained for steady progress. One example might be Chomsky's program of universal grammar whose inductive complexity hinges on how broad we assume the set of humanly learnable languages to be. It is an interesting question how much the complexity of an empirical investigation, as determined by the strength of the available background assumptions, connects with the practitioners' sense of progress and feasibility. In the domains considered so far, learning-theoretic complexity corresponds quite well to intuitive methodological difficulty, but more case studies are required. In any case, learning-theoretic characterization theorems help us to pinpoint the sources of inductive complexity, and thus the methodologically central assumptions and the weak spots in a given empirical enterprise.

3. *Universal Measure of Inductive Complexity*. There are characterization theorems for a number of standards of empirical success. The more demanding the standard, the more stringent the conditions that such standards require. It turns out that a number of natural standards of inductive success fall into a hierarchy of feasibility, in the sense that standards higher in the hierarchy are attainable if standards lower in the hierarchy are. For a trivial example, if it is possible to settle on a correct hypothesis with at most 5 mind changes, then a fortiori it is possible to succeed with 10 mind changes. For other cognitive aims the inclusion is more surprising; see Schulte [1999a]. We may think of the hierarchy of standards of empirical success as establishing a scale for inductive problems: The more difficult the problem, the less we can expect from inquiry. The hierarchy of empirical success allows us to weigh such diverse problems as Goodman's Riddle, particle dynamics and language learning on the same scale. For example, it should be clear that the characteristic condition for reliable inquiry -- - that each hypothesis be equivalent to a countable disjunction of refutable assertions -- applies in every domain of investigation. Thus means-ends analysis uncovers common structure among seemingly disparate problems.

4. *Language Invariance*. Learning-theoretic characterization theorems concern what Kelly calls the "temporal entanglement" of various observation sequences [Kelly 2000] (see also [Schulte and Juhl 1996]). Ultimately they rest on entailment relations between given evidence, background assumptions and empirical claims. Since logical entailment does not depend on the language we use to frame evidence and hypotheses, the inductive complexity of an empirical problem as determined by the characterization theorems is language-invariant. Indeed, it turns out that inductive complexity can be captured in terms of point-set topology and corresponds to a scale of topological complexity that has much importance in mathematics (the Borel and finite-difference hierarchies [Kelly 1996]).

5. Categorical vs. Hypothetical Imperatives

Kant distinguished between categorical imperatives that one ought to follow regardless of one's personal aim and circumstances, and hypothetical imperatives that direct us to employ our means towards our chosen end. One way to think of learning theory is as the study of hypothetical imperatives for empirical inquiry. Many epistemologists have proposed various categorical imperatives for inductive inquiry, for example in the form of an "inductive logic" or norms of "epistemic rationality". In principle, there are three possible relationships between hypothetical and categorical imperatives for empirical inquiry.

1. The categorical imperative will lead an inquirer to obtain his cognitive goals. In that case means-ends analysis *vindicates* the categorical imperative. For example, when faced with a simple universal generalization such as "all ravens are black", we saw above that following the Popperian recipe of adopting the falsifiable generalization and sticking to it until a counter example appears leads to a reliable method.

2. The categorical imperative may *prevent* an inquirer from achieving his aims. In that case the categorical imperative *restricts* the scope of inquiry. For example, in the case of the two alternative generalizations with exceptions, the principle of maintaining a universal generalization until it is falsified leads to an unreliable method (cf. [Kelly 1996, Ch. 9.4]).

3. Some methods meet *both* the categorical imperative and the goals of inquiry, and others don't. Then we may take the best of both worlds and choose those methods that attain the goals of inquiry and satisfy categorical imperatives. (See the further

discussion in this section.)

For a proposed norm of inquiry, we can apply means-ends analysis to ask whether the norm helps or hinders the aims of inquiry. This was the spirit of Putnam's critique of Carnap's confirmation functions [Putnam 1963]: the thrust of his essay was that Carnap's methods were not as reliable in detecting general patterns as other methods would be. More recently, learning theorists have investigated the power of Bayesian conditioning (see the entry on Bayesian epistemology). John Earman has conjectured that if there is any reliable method for a given problem, then there is a reliable method that proceeds by Bayesian updating [Earman 1992, Ch.9, Sec.6]. Cory Juhl [1997] provided a partial confirmation of Earman's conjecture: He proved that it holds when there are only two potential evidence items (e.g., "emerald is green" vs. "emerald is blue"). The general case is still open.

Epistemic conservatism is a methodological norm that has been prominent in philosophy at least since Quine's notion of "minimal mutilation" of our beliefs [1951]. One version of epistemic conservatism, as we saw above, holds that inquiry should seek stable belief. Another formulation, closer to Quine's, is the general precept that belief changes in light of new evidence should be minimal. Fairly recent work in philosophical logic has proposed a number of criteria for *minimal belief change* known as the AGM axioms [Gärdenfors 1988]. Learning theorists have shown that whenever there is a reliable method for investigating an empirical question, there is one that proceeds via minimal changes (as defined by the AGM postulates). The properties of reliable inquiry with minimal belief changes are investigated in [Kelly et al. 1995, Martin and Osherson 1998, Kelly 1999].

Much of computational learning theory focuses on inquirers with *bounded rationality*, that is, agents with cognitive limitations such as a finite memory or bounded computational capacities. Many categorical norms that do not interfere with empirical success for logically omniscient agents nonetheless limit the scope of cognitively bounded agents. For example, consider the norm of consistency: Believe that a hypothesis is false as soon as the evidence is logically inconsistent with it. The consistency principle is part of both Bayesian confirmation theory and AGM belief revision. Kelly and Schulte [1995] show that consistency prevents even agents with infinitely uncomputable cognitive powers from reliably assessing certain hypotheses. The moral is that if a theory is sufficiently complex, agents who are not logically omniscient may be unable to determine immediately whether a given piece of evidence is consistent with the theory, and need to collect more data to detect the inconsistency. But the consistency principle -- and a fortiori, Bayesian updating and AGM belief revision -- rule out this kind of scientific strategy.

More reflection on this and other philosophical issues in means-ends epistemology can be found in sources such as [Glymour 1991], [Kelly 1996, Chs. 2,3], [Glymour and Kelly 1992], [Kelly *et al*. 1997], [Schulte and Juhl 1996], [Glymour 1994], [Bub 1994]. Of particular interest in the philosophy of science may be learning-theoretic models that accommodate historicist and relativist conceptions of inquiry, chiefly by expanding the notion of an inductive method so that methods may actively select paradigms for inquiry; for more details on this topic, see [Kelly 2000, Kelly 1996, Ch.13]. Booklength introductions to the mathematics of learning theory are [Kelly 1996, Martin and Osherson 1998, Jain et al. 1999].

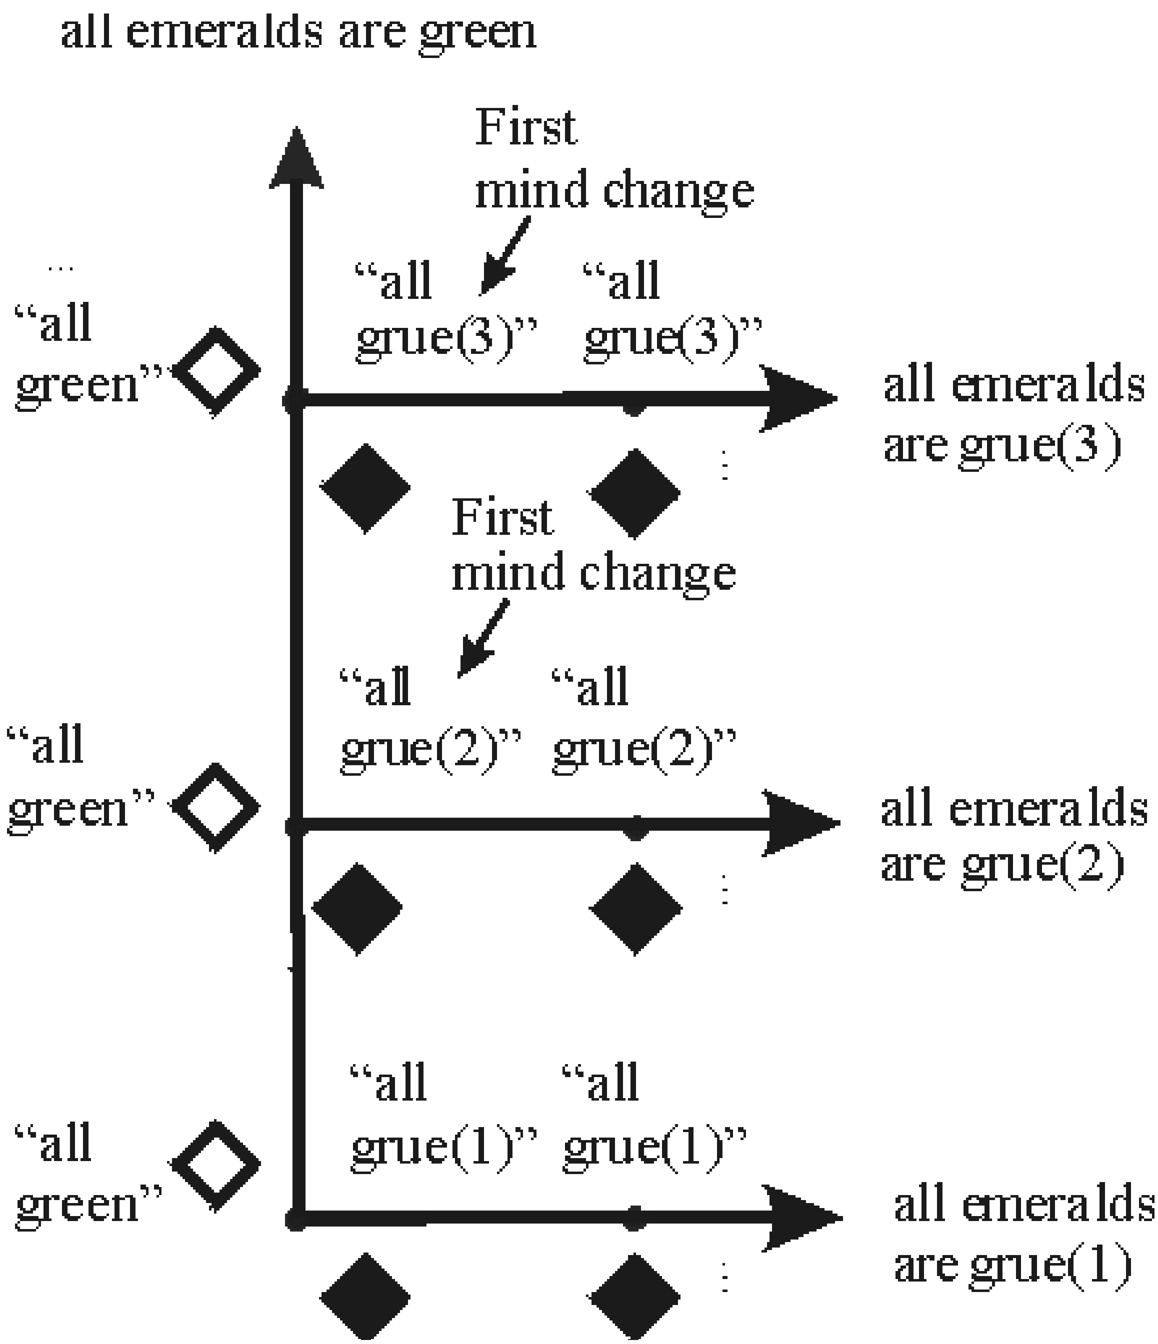
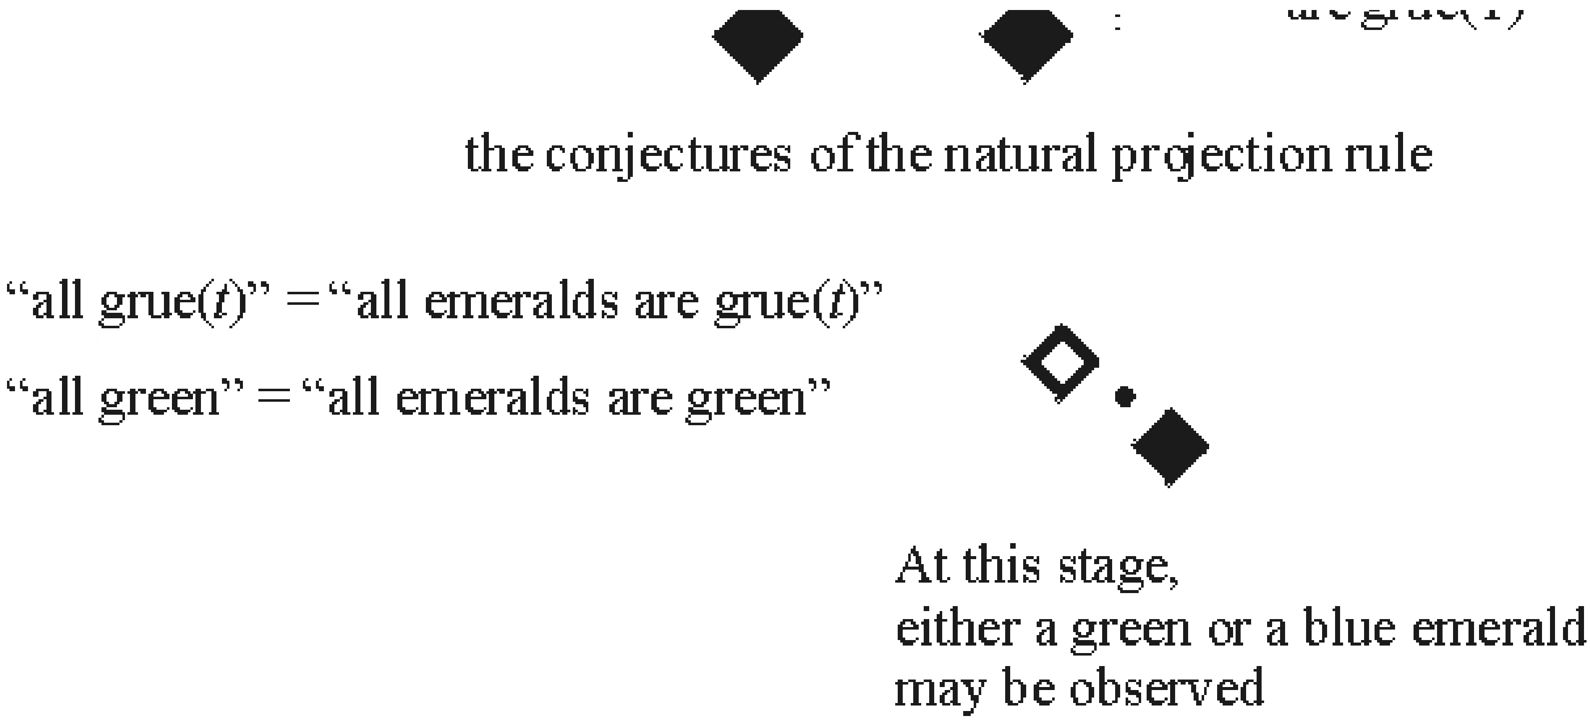
Supplement to Formal Learning Theory

Basic Formal Definitions

The purpose of this supplement is a concise formal development of the basic notions of learning theory so as to make mathematical treatments of the subject more accessible to the reader. Also, the supplement develops some of the concepts discussed in the main entry in formal language. For the most part I follow Kelly's [1996] treatment which is at once more general and simpler than other approaches. The discussion below illustrates concepts by reference to the Goodmanian Riddle of Induction; the figure illustrating this inductive problem is reproduced here.





Evidence, Hypotheses and Discovery Problems

The basic building block of formal learning theory is the notion of an **evidence item**. For a general formulation, we may simply begin with a set *E* of evidence items. In general, nothing need be assumed about this set; in what follows, I will assume that *E* is at most countable, that is, that there are at most countably many evidence items. Some authors assume that evidence is formulated in first-order logic, typically as literals (e.g., [Earman 1992], [Martin and Osherson 1988]). In formal models of language learning, the evidence items are strings, representing grammatical strings from the language to be learned. In the example of the Riddle of Induction, the evidence items are G and B, respectively represented in the picture by a transparent and by a filled diamond, so *E* = {G,B}.

Given the basic set *E* of evidence items, we have the notion of a **finite evidence sequence**. A finite evidence sequence is a sequence (e_1, e_2, ..., e_n) of evidence items, that is, members of *E*. For example, the observation that the first three emeralds are green corresponds to the evidence sequence (G,G,G). A typical notation for a finite evidence sequence is *e*. If a finite evidence sequence *e* has *n* members, we say that the sequence is of length *n* and write *lh*(*e*) = *n*.

The next step is to consider an **infinite evidence sequence**. An infinite evidence sequence is a sequence (e_1, e_2, ..., e_n, ...) that continues indefinitely. For example, the infinite sequence (G,G,G,...,G,....) represents the circumstance in which all observed emeralds are green. A typical notation for an infinite evidence sequence is ε. Following Kelly [1996], the remainder of this supplement refers to an infinite evidence sequence as a **data stream**. Even though the notion of an infinite data sequence is mathematically straightforward, it takes some practice to get used to employing it. We often have occasion to refer to finite initial segments of a data stream, and introduce some special notation for this purpose: Let ε|*n* denote the first *n* evidence items in the data stream ε. For example if ε = (G,G,G,...,G,...) is the data stream featuring only green emeralds, then ε|3 = (G,G,G) is the finite evidence sequence corresponding to the observation

that the first three emeralds are green. We also write ε_n to denote the *n*-th evidence item observed in ε. For example, if ε = (G,G,G,...,G,...), then ε_2 = G.

An **empirical hypothesis** is a claim whose truth supervenes on a data stream. That is, a complete infinite sequence of observations settles whether or not an empirical hypothesis is true. For example, the hypothesis that "all observed emeralds are green" is true on the data stream featuring only green emeralds, and false on any data stream featuring a nongreen emerald. In general, we assume that a **correctness relation** *C* has been specified, where $C(\varepsilon,H)$ holds just in case hypothesis *H* is correct an data stream ε. What hypotheses are taken as correct on which data streams is a matter of the particular application. Given a correctness relation, we can define the empirical content of a hypothesis *H* as the set of data streams on which *H* is correct. Thus the empirical content of hypothesis *H* is given by $\{\varepsilon: C(\varepsilon, H)\}$. For formal purposes, it is often easiest to dispense with the correctness relation and simply to identify hypotheses with their empirical content. With that understanding, in what follows hypotheses will often be viewed as **sets of data streams**. For ease of exposition, I do not always distinguish between a hypothesis viewed as a set of data streams and an expression denoting that hypothesis, such as "all emeralds are green".

An inquirer typically does not begin inquiry as a tabula rasa, but has background assumptions about what the world is like. To the extent that such background assumptions help in inductive inquiry, they restrict the space of possible observations. For example in the discussion of the Riddle of Induction above, I assumed that that no data stream will be obtained that has green emeralds followed by blue emeralds followed by green emeralds. In the conservation principle problem discussed in the main entry, the operative background assumption is that the complete particle dynamics can be accounted for with conservation principles. As with hypotheses, we can represent the empirical content of given background assumptions by a set of data streams. Again it is simplest to identify **background knowledge** *K* with a set of data streams, namely the ones consistent with the background knowledge.

In a logical setting in which evidence statements are literals, learning theorists typically assume that a given data stream will feature all literals of the given first-order language (statements such as P(a) or ¬P(a)), and that the total set of evidence statements obtained during inquiry is consistent. With that background assumption, we may view the formula $\forall$x.P(x) as an empirical hypothesis that is correct on an infinite evidence sequence ε just in case no literal ¬P(a) appears on ε, that is for all *n* it is the case that $\varepsilon_n \neq \neg P(a)$. More generally, a data stream with a complete, consistent enumeration of literals determines the truth of every quantified statement in the given first-order language.

Inductive Methods and Inductive Success

An **inductive method** is a function that assigns hypotheses to finite evidence sequences. Following Kelly [1996], I use the symbol δ for an inductive method. Thus if *e* is a finite evidence sequence, then $\delta(e) = H$ expresses the fact that on finite evidence sequence *e*, the method δ outputs hypothesis *H*. It is also possible to have a method δ assign probabilities to hypotheses rather than choose a single conjecture, but I leave this complication aside here. Inductive methods are also called "learners" or "scientists"; no matter what the label is, the mathematical concept is the same. In the Goodmanian Riddle above, the natural projection

rule outputs the hypothesis "all emeralds are green" on any finite sequence of green emeralds. Thus if we denote the natural projection rule by δ, and the hypothesis that all emeralds are green by "all G", we have that δ(G) = "all G", δ(GG) = "all G", and so forth. Letting ε = (G,G,G,...,G,...) be the data stream with all green emeralds, we can write $\varepsilon|1$ = (G), $\varepsilon|2$ = (GG), etc., so we have that $\delta(\varepsilon|1)$ = "all G", $\delta(\varepsilon|2)$ = "all G", and more generally that $\delta(\varepsilon|n)$ = "all G" for all *n*.

An inductive method δ **converges to** a hypothesis *H* on a data stream ε **by time *n*** just in case for all later times $n' \geq n$, we have that $\delta(\varepsilon|n') = H$. This is a central definition for defining empirical success, as we will see shortly. To illustrate, the natural projection rule converges to "all G" by time 1 on the data stream ε = (G,G,G,...,G,...). It converges to "all emeralds are grue(3)" by time 3 on the data stream (G,G,B,B,B, ...). An inductive method δ **converges to** a hypothesis *H* on a data stream ε just in case there is a time *n* such that δ converges to *H* on ε by time *n*. Thus on the data stream (G,G,G...), the natural projection δ converges to "all G" whereas on the data stream (G,G,B,B,...) this rule converges to "all emeralds are grue(3)".

A **discovery problem** is a pair (**H**, *K*) where *K* is a set of data streams representing background knowledge and **H** is a mutually exclusive set of hypotheses that covers *K*. That is, for any two hypotheses *H*, *H'* in **H**, viewed as two sets of data streams, we have that $H \cap H' = \varnothing$. And for any data stream ε in K, there is a (unique) hypothesis *H* in **H** such that $\varepsilon \in H$. For example, in the Goodmanian Riddle of Induction, each alternative hypothesis is a singleton containing just one data stream, for example {(G,G,G,...)} for the empirical content of "all emeralds are green". The background knowledge *K* is just the union of the alternative hypotheses. In the problem involving the generalizations "all but finitely many ravens are white" and "all but finitely many ravens are black", the former hypothesis corresponds to the set of data streams featuring only finitely many black ravens, and the latter to the set of data streams featuring only finitely many white ravens. The background knowledge *K* corresponds to the set of data streams that eventually feature only white ravens or eventually feature only black ravens. Since each alternative hypothesis in a discovery problem (**H**, *K*) is mutually exclusive, for a given data stream ε in *K* there is exactly one hypothesis correct for that data stream; I write $H(\varepsilon)$ to denote that hypothesis.

In a discovery problem (**H**, *K*), an inductive method δ **succeeds** on a data stream ε in *K* iff δ converges to the hypothesis correct for ε; more formally, δ **succeeds** on a data stream ε in *K* iff δ converges to $H(\varepsilon)$ on ε. An inductive method δ **solves** the discovery problem (**H**, *K*) iff δ succeeds on all data streams in *K*. If δ solves a discovery problem (**H**, *K*), then we also say that δ is **reliable** for (**H**, *K*). If there is a reliable inductive method δ for a discovery problem (**H**, *K*), we say that the problem (**H**, *K*) is **solvable**. The main entry presented several solvable discovery problems. Characterization theorems like the one discussed there give conditions under which a discovery problem is solvable.

Efficient inductive inquiry is concerned with maximizing epistemic values other than convergence to the truth. Minimizing the number of mind changes is a topic in the main entry; what follows defines this measure of inductive performance as well as error and convergence time. Consider a discovery problem (**H**, *K*) and a data stream ε in *K*.

1. The **convergence time**, or **modulus**, of a method δ on ε is the least time *n* by which δ converges to a hypothesis *H* on ε. If δ is a reliable method for (**H**, *K*), then δ converges to a hypothesis on every data stream ε consistent with background knowledge *K* -- more specifically, δ converges to the correct hypothesis $H(\varepsilon)$ -- and the convergence time of δ is well-defined.
2. An inductive method δ **commits an error** at time *n* on ε iff $\delta(\varepsilon|n)$ is false, i.e., if $\delta(\varepsilon|n) \neq H(\varepsilon)$. As with convergence time, if δ is reliable, then it makes only finitely many errors on any data stream consistent with background knowledge. The number of errors commited by δ on a data stream ε is thus given by $|\{n: \delta(\varepsilon|n) \neq H(\varepsilon)\}|$.
3. To count mind changes (and errors) properly, it is useful to allow methods to produce an "uninformative conjecture" ?, which we may think of as a tautologous proposition. The point is that we don't want to count a change from "no opinion" to an informative hypothesis as a mind change. This device allows us to represent methods that "wait" until further evidence before taking an "inductive leap". Formally we say that an inductive method δ **changes its mind** at time *n*+1 on ε iff the method's previous conjecture at time *n* was informative and changes at time *n*+1. In symbols, δ **changes its mind** at time *n*+1 on ε iff: $\delta(\varepsilon|n) \neq ?$ and $\delta(\varepsilon|n) \neq \delta(\varepsilon|n+1)$. The number of mind changes made by δ on a data stream ε is thus given by $|\{n: \delta$ changes its mind on ε at time $n\}|$.

As we saw in the main entry, assessing methods by how well they do vis-a-vis these criteria of cognitive success leads to restrictions on inductive inferences in the short run, sometimes very strong restrictions. Learning-theoretic characterization theorems specify the structure of problems in which efficient inquiry is possible, and what kind of inferences lead to inductive success when it is attainable.

Return to Formal Learning Theory

First published: February 2, 2002
Content last modified: February 2, 2002

Bayesian Epistemology

‘Bayesian epistemology’ became an epistemological movement in the 20th century, though its two main features can be traced back to the eponymous Reverend Thomas Bayes (c. 1701-61). Those two features are: (1) the introduction of a *formal apparatus* for inductive logic; (2) the introduction of a *pragmatic self-defeat test* (as illustrated by Dutch Book Arguments) for *epistemic* rationality as a way of extending the justification of the laws of deductive logic to include a justification for the laws of inductive logic. The formal apparatus itself has two main elements: the use of the laws of probability as coherence constraints on rational degrees of belief (or degrees of confidence) and the introduction of a rule of probabilistic inference, a rule or principle of *conditionalization*.

Bayesian epistemology did not emerge as a philosophical program until the first formal axiomatizations of probability theory in the first half of the 20th century. One important application of Bayesian epistemology has been to the analysis of scientific practice in *Bayesian Confirmation Theory*. In addition, a major branch of statistics, *Bayesian statistics*, is based on Bayesian principles. In psychology, an important branch of learning theory, *Bayesian learning theory*, is also based on Bayesian principles. Finally, the idea of analyzing rational degrees of belief in terms of rational betting behavior led to the 20th century development of a new kind of decision theory, *Bayesian decision theory*, which is now the dominant theoretical model for the both the descriptive and normative analysis of decisions. The combination of its precise formal apparatus and its novel pragmatic self-defeat test for justification makes Bayesian epistemology one of the most important developments in epistemology in the 20th century, and one of the most promising avenues for further progress in epistemology in the 21st century.

1. Deductive and Probabilistic Coherence and Deductive and Probabilistic Rules of Inference

There are two ways that the laws of deductive logic have been thought to provide rational constraints on belief: (1) Synchronically, the laws of deductive logic can be used to define the notion of deductive consistency and inconsistency. Deductive inconsistency so defined determines one kind of incoherence in belief, which I refer to as *deductive incoherence*. (2) Diachronically, the laws of deductive logic can constrain admissible changes in belief by providing the *deductive rules of inference*. For example, *modus ponens* is a deductive rule of inference that requires that one infer Q from premises P and $P \rightarrow Q$.

Bayesians propose additional standards of synchronic coherence -- standards of *probabilistic coherence* -- and additional rules of inference -- *probabilistic rules of inference* -- in both cases, to apply not to beliefs, but degrees of belief (degrees of confidence). For Bayesians, the most important standards of probabilistic coherence are the laws of probability. For more on the laws of probability, see the following supplementary article:

> Supplement on Probability Laws

For Bayesians, the most important probabilistic rule of inference is given by a p*rinciple of conditionalization*.

2. A Simple Principle of Conditionalization

If unconditional probabilities (e.g. $P(S)$) are taken as primitive, the conditional probability of S on T can be defined as follows:

> **Conditional Probability**:
> $P(S/T) = P(S\&T)/P(T)$.

By itself, the definition of conditional probability is of little epistemological significance. It acquires epistemological significance only in conjunction with a further epistemological assumption:

> **Simple Principle of Conditionalization**:
> If one begins with initial or *prior* probabilities P_i, and one acquires new evidence which can be represented as becoming certain of an evidentiary statement E (assumed to state the totality of one's new evidence and to have initial probability greater than zero), then rationality requires that one systematically transform one's initial probabilities to generate final or *posterior* probabilities P_f by conditionalizing on E -- that is: Where S is any statement, $P_f(S) = P_i(S/E)$.[1]

In epistemological terms, this Simple Principle of Conditionalization requires that the effects of evidence on rational degrees be analyzed in two stages: The first is non-inferential. It is the change in the probability of the evidence statement E from $P_i(E)$, assumed to be greater than zero and less than one, to $P_f(E) = 1$. The second is a probabilistic inference of conditionalizing on E from initial probabilities (e.g., $P_i(S)$) to final probabilities (e.g., $P_f(S) = P_i(S/E)$).

Problems with the Simple Principle (to be discussed below) have led many Bayesians to qualify the Simple Principle by limiting its scope. In addition, some Bayesians follow Jeffrey in generalizing the Simple Principle to apply to cases in which one's new evidence is less than certain (also discussed below). What unifies Bayesian epistemology is a conviction that conditionalizing (perhaps of a generalized sort) is rationally required in some important contexts -- that is, that some sort of conditionalization principle is an important principle governing rational changes in degrees of belief.

3. Dutch Book Arguments

Many arguments have been given for regarding the probability laws as coherence conditions on degrees of belief and for taking some principle of conditionalization to be a rule of probabilistic inference. The most distinctively Bayesian are those referred to as *Dutch Book Arguments*. Dutch Book Arguments represent the possibility of a new kind of justification for epistemological principles.

A Dutch Book Argument relies on some descriptive or normative assumptions to connect degrees of belief with willingness to wager -- for example, a person with degree of belief p in sentence S is assumed to be willing to pay up to and including $\$p$ for a unit wager on S (i.e., a wager that pays \$1 if S is true) and is willing to sell such a wager for any price equal to or greater than $\$p$ (one is assumed to be equally willing to buy or sell such a wager when the price is exactly $\$p$).[2] A *Dutch Book* is a combination of wagers which, on the basis of deductive logic alone, can be shown to entail a sure loss. A *synchronic Dutch Book* is a Dutch Book combination of wagers that one would accept all at the same time. A *diachronic Dutch Book* is a Dutch Book combination of wagers that one will be motivated to enter into at different times.

Ramsey and de Finetti first employed synchronic Dutch Book Arguments in support of the probability laws as standards of synchronic coherence for degrees of belief. The first diachronic Dutch Book Argument in support of a principle of conditionalization was reported by Teller, who credited David Lewis. The Lewis/Teller argument depends on a further descriptive or normative assumption about conditional probabilities due to de Finetti: An agent with conditional probability $P(S/T) = p$ is assumed to be willing to pay any price up to and including $\$p$ for a unit wager on S conditional on T. (A unit wager on S conditional on T is one that is called off, with the purchase price returned to the purchaser, if T is not true. If T is true, the wager is not called off and the wager pays \$1 if S is also true.) On this interpretation of conditional probabilities, Lewis, as reported by Teller, was able to show how to construct a diachronic Dutch Book against anyone who, on learning only that T, would predictably change his/her degree of belief in S to $P_f(S) > P_i(S/T)$; and how to construct a diachronic Dutch Book against anyone who, on

learning only that *T*, would predictably change his/her degree of belief in *S* to $P_f(S) < P_i(S/T)$. For illustrations of the strategy of the Ramsey/de Finetti and the Lewis/Teller arguments, see the following supplementary article:

> Supplement on Dutch Book Arguments

There has been much discussion of exactly what it is that Dutch Book Arguments are supposed to show. On the *literal-minded interpretation*, their significance is that they show that those whose degrees of belief violate the probability laws or those whose probabilistic inferences predictably violate a principle of conditionalization are liable to enter into wagers on which they are sure to lose. There is very little to be said for the literal-minded interpretation, because there is no basis for claiming that rationality requires that one be willing to wager in accordance with the behavioral assumptions described above. An agent could simply refuse to accept Dutch Book combinations of wagers.

A more plausible interpretation of Dutch Book Arguments is that they are to be understood hypothetically, as symptomatic of what has been termed *pragmatic self-defeat*. On this interpretation, Dutch Book Arguments are a kind of heuristic for determining when one's degrees of belief have the potential to be *pragmatically self-defeating*. The problem is not that one who violates the Bayesian constraints is likely to enter into a combination of wagers that constitute a Dutch Book, but that, on any reasonable way of translating one's degrees of belief into action, there is a potential for one's degrees of belief to motivate one to act in ways that make things worse than they might have been, when, as a matter of logic alone, it can be determined that alternative actions would have made things better (on one's own evaluations of better and worse).

Another way of understanding the problem of susceptibility to a Dutch Book is due to Ramsey: Someone who is susceptible to a Dutch Book evaluates identical bets differently based on how they are described. Putting it this way makes susceptibility to Dutch Books sound irrational. But this standard of rationality would make it irrational not to recognize all the logical consequences of what one believes. This is the *assumption of logical omniscience* (discussed below).

If successful, Dutch Book Arguments would reduce the justification of the principles of Bayesian epistemology to two elements: (1) an account of the appropriate relationship between degrees of belief and choice; and (2) the laws of deductive logic. Because it would seem that the truth about the appropriate relationship between the degrees of belief and choice is independent of epistemology, Dutch Book Arguments hold out the potential of justifying the principles of Bayesian epistemology in a way that requires no other epistemological resources than the laws of deductive logic. For this reason, it makes sense to think of Dutch Book Arguments as indirect, pragmatic arguments for according the principles of Bayesian epistemology much the same epistemological status as the laws of deductive logic. Dutch Book Arguments are a truly distinctive contribution made by Bayesians to the methodology of epistemology.

It should also be mentioned that some Bayesians have defended their principles more directly, with non-pragmatic arguments. In addition to reporting Lewis's Dutch Book Argument, Teller offers a non-

pragmatic defense of Conditionalization. There have been many proposed non-pragmatic defenses of the probability laws, the most compelling of which is due to Joyce. All such defenses, whether pragmatic or non-pragmatic, produce a puzzle for Bayesian epistemology: The principles of Bayesian epistemology are typically proposed as principles of *inductive* reasoning. But if the principles of Bayesian epistemology depend ultimately for their justification solely on the laws of deductive logic, what reason is there to think that they have any *inductive* content? That is to say, what reason is there to believe that they do anything more than extend the laws of deductive logic from beliefs to degrees of belief? It should be mentioned, however, that even if Bayesian epistemology only extended the laws of deductive logic to degrees of belief, that alone would represent an extremely important advance in epistemology.

4. Bayes' Theorem and Bayesian Confirmation Theory

This section reviews some of the most important results in the Bayesian analysis of scientific practice -- *Bayesian Confirmation Theory*. It is assumed that all statements to be evaluated have prior probability greater than zero and less than one.

Bayes' Theorem and a Corollary

Bayes' Theorem is a straightforward consequence of the probability axioms and the definition of conditional probability:

> **Bayes' Theorem**:
> $P(S/T) = P(T/S) \times P(S)/P(T)$ [where $P(T)$ is assumed to be greater than zero]

The epistemological significance of Bayes' Theorem is that it provides a straightforward corollary to the Simple Principle of Conditionalization. Where the final probability of a hypothesis *H* is generated by conditionalizing on evidence *E*, Bayes' Theorem provides a formula for the final probability of *H* in terms of the prior or initial *likelihood* of *H* on *E* ($P_i(E/H)$) and the prior or initial probabilities of *H* and *E*:

> **Corollary of the Simple Principle of Conditionalization**:
> $P_f(H) = P_i(H/E) = P_i(E/H) \times P_i(H)/P_i(E)$.

Due to the influence of Bayesianism, *likelihood* is now a technical term of art in confirmation theory. As used in this technical sense, likelihoods can be very useful. Often, when the conditional probability of *H* on *E* is in doubt, the likelihood of *H* on *E* can be computed from the theoretical assumptions of *H*.

Bayesian Confirmation Theory

A. Confirmation and disconfirmation. In Bayesian Confirmation Theory, it is said that evidence

confirms (or would confirm) hypothesis *H* (to at least some degree) just in case the prior probability of *H* conditional on *E* is greater than the prior unconditional probability of *H*: $P_i(H/E) > P_i(H)$. *E* disconfirms (or would disconfirm) *H* if the prior probability of *H* conditional on *E* is less than the prior unconditional probability of *H*.

B. Confirmation and disconfirmation by entailment. Whenever a hypothesis *H* logically entails evidence *E*, *E* confirms *H*. This follows from the fact that to determine the truth of *E* is to rule out a possibility assumed to have non-zero prior probability that is incompatible with *H* -- the possibility that ~*E*. A corollary is that, where *H* entails *E*, ~*E* would disconfirm *H*, by reducing its probability to zero. The most influential model of explanation in science is the hypothetico-deductive model (e.g., Hempel). Thus, one of the most important sources of support for Bayesian Confirmation Theory is that it can explain the role of hypothetico-deductive explanation in confirmation.

C. Confirmation of logical equivalents. If two hypotheses H1 and H2 are logically equivalent, then evidence *E* will confirm both equally. This follows from the fact that logically equivalent statements always are assigned the same probability.

D. The confirmatory effect of surprising or diverse evidence. From the corollary above, it follows that whether *E* confirms (or disconfirms) *H* depends on whether *E* is more probable (or less probable) conditional on *H* than it is unconditionally -- that is, on whether:

(b1) $P(E/H)/P(E) > 1$.

An intuitive way of understanding (b1) is to say that it states that *E* would be more expected (or less surprising) if it were known that *H* were true. So if *E* is surprising, but would not be surprising if we knew *H* were true, then *E* will significantly confirm *H*. Thus, Bayesians explain the tendency of surprising evidence to confirm hypotheses on which the evidence would be expected.

Similarly, because it is reasonable to think that evidence E_1 makes other evidence of the same kind much more probable, after E_1 has been determined to be true, other evidence of the same kind E_2 will generally not confirm hypothesis *H* as much as other diverse evidence E_3, even if *H* is equally likely on both E_2 and E_3. The explanation is that where E_1 makes E_2 much more probable than E_3 ($P_i(E_2/E_1) >> P_i(E_3/E_1)$), there is less potential for the discovery that E_2 is true to raise the probability of *H* than there is for the discovery that E_3 is true to do so.

E. Relative confirmation and likelihood ratios. Often it is important to be able to compare the effect of evidence *E* on two competing hypotheses, H_j and H_k, without having also to consider its effect on other hypotheses that may not be so easy to formulate or to compare with H_j and H_k. From the first corollary above, the ratio of the final probabilities of H_j and H_k would be given by:

Ratio Formula:

$$P_f(H_j)/P_f(H_k) = [P_i(E/H_j) \times P_i(H_j)]/[P_i(E/H_k) \times P_i(H_k)]$$

If the *odds of* H_j *relative to* H_k are defined as ratio of their probabilities, then from the Ratio Formula it follows that, in a case in which change in degrees of belief results from conditionalizing on E, the final odds ($P_f(H_j)/P_f(H_k)$) result from multiplying the initial odds ($P_i(H_j)/P_i(H_k)$) by the *likelihood ratio* ($P_i(E/H_j)/P_i(E/H_k)$). Thus, in pairwise comparisons of the odds of hypotheses, the likelihood ratio is the crucial determinant of the effect of the evidence on the odds.

F. The typical differential effect of positive evidence and negative evidence. Hempel first pointed out that we typically expect the hypothesis that all ravens are black to be confirmed to some degree by the observation of a black raven, but not by the observation of a non-black, non-raven. Let H be the hypothesis that all ravens are black. Let E_1 describe the observation of a non-black, non-raven. Let E_2 describe the observation of a black raven. Bayesian Confirmation Theory actually holds that both E_1 and E_2 may provide some confirmation for H. Recall that E_1 supports H just in case $P_i(E_1/H)/P_i(E_1) > 1$. It is plausible to think that this ratio is ever so slightly greater than one. On the other hand, E_2 would seem to provide much greater confirmation to H, because, in this example, it would be expected that $P_i(E_2/H)/P_i(E_2) >> P_i(E_1/H)/P_i(E_1)$.

These are only a sample of the results that have provided support for Bayesian Confirmation Theory as a theory of rational inference for science. For further examples, see Howson and Urbach. It should also be mentioned that an important branch of statistics, *Bayesian statistics* is based on the principles of Bayesian epistemology.

5. Potential Problems

This section reviews some of the most important potential problems for Bayesian Confirmation Theory and for Bayesian epistemology generally. No attempt is made to evaluate their seriousness here, though there is no generally agreed upon Bayesian solution to any of them.

5.1 Objections to the Probability Laws as Standards of Synchronic Coherence

A. The assumption of logical omniscience. The assumption that degrees of belief satisfy the probability laws implies omniscience about deductive logic, because the probability laws require that all deductive logical truths have probability one, all deductive inconsistencies have probability zero, and the probability of any conjunction of sentences be no greater than *any* of its deductive consequences. This seems to be an unrealistic standard for human beings. Hacking and Garber have made proposals to relax the assumption of logical omniscience. Because relaxing that assumption would block the derivation of almost all the important results in Bayesian epistemology, most Bayesians maintain the assumption of logical omniscience and treat it as an ideal to which human beings can only more or less approximate.

B. The problem of the priors. Are there constraints on prior probabilities other than the probability laws? Consider Goodman's "new riddle of induction": In the past all observed emeralds have been green. Do those observations provide any more support for the generalization that all emeralds are green than they do for the generalization that all emeralds are grue (green if observed before now; blue if observed later); or do they provide any more support for the prediction that the next emerald observed will be green than for the prediction that the next emerald observed will be grue (i.e., blue)? This question divides Bayesians into two categories:

> (a) *Objective Bayesians* (e.g., Rosenkrantz) hold that there are rational constraints on prior probabilities that require that observations support the green-generalization and the green-prediction much more strongly than the grue-generalization and the grue-prediction. Objective Bayesians are the intellectual heirs of the advocates of a Principle of Indifference for probability. Rosenkrantz builds his account on the maximum entropy rule proposed by E.T. Jaynes. The difficulties in formulating an acceptable Principle of Indifference have led most Bayesians to abandon Objective Bayesianism.
>
> (b) *Subjective Bayesians* (e.g., de Finetti) do not believe that rationality alone places enough constraints on one's prior probabilities to make them objective. For Subjective Bayesians, it is up to our own free choice or to evolution or to socialization or some other non-rational process to determine one's prior probabilities. Rationality only requires that the prior probabilities satisfy relatively modest synchronic coherence conditions.

Subjective Bayesians believe that their position is not objectionably subjective, because of results (e.g., Doob or Gaifman and Snir) proving that even subjects beginning with very different prior probabilities will tend to converge in their final probabilities, given a suitably long series of shared observations. These *convergence results* are not completely reassuring, however, because they only apply to agents who already have significant agreement in their priors and they do not assure convergence in any reasonable amount of time. Also, they typically only guarantee convergence on the probability of predictions, not on the probability of theoretical hypotheses. For example, Carnap favored prior probabilities that would never raise above zero the probability of a generalization over a potentially infinite number of instances (e.g., that all crows are black), no matter how many observations of positive instances (e.g., black crows) one might make without finding any negative instances (i.e., non-black crows). In addition, the convergence results depend on the assumption that the *only* changes in probabilities that occur are those that are the non-inferential results of observation on evidential statements and those that result from conditionalization on such evidential statements.

Because of the problem of the priors, it is an open question whether Bayesian Confirmation Theory has inductive content, or whether it merely translates the framework for rational belief provided by deductive logic into a corresponding framework for rational degrees of belief.

5.2 Objections to The Simple Principle of Conditionalization as a Rule

of Inference, Especially as an Explanation of Theory Confirmation in Science

A. The problem of uncertain evidence. The Simple Principle of Conditionalization requires that the acquisition of evidence be representable as changing one's degree of belief in a statement *E* to one -- that is, to certainty. But many philosophers would object to assigning probability of one to any contingent statement, even an evidential statement, because, for example, it is well-known that scientists sometimes give up previously accepted evidence. Jeffrey has proposed a generalization of the Principle of Conditionalization that yields that principle as a special case. Jeffrey's idea is that what is crucial about observation is not that it yields certainty, but that it generates a non-inferential change in the probability of an evidential statement *E* and its negation ~*E* (assumed to be the locus of all the non-inferential changes in probability) from initial probabilities between zero and one to $P_f(E)$ and $P_f(\sim E) = [1 - P_f(E)]$. Then on Jeffrey's account, after the observation, the rational degree of belief to place in an hypothesis *H* would be given by the following principle:

> **Principle of Jeffrey Conditionalization**:
> $P_f(H) = P_i(H/E) \times P_f(E) + P_i(H/\sim E) \times P_f(\sim E)$ [where *E* and *H* are both assumed to have prior probabilities between zero and one]

Counting in favor of Jeffrey's Principle is its theoretical elegance. Counting against it is the practical problem that it requires that one be able to completely specify the direct non-inferential effects of an observation, something it is doubtful that anyone has ever done. Skyrms has given it a Dutch Book defense.

B. The problem of old evidence. On a Bayesian account, the effect of evidence *E* in confirming (or disconfirming) a hypothesis is solely a function of the increase in probability that accrues to *E* when it is first determined to be true. This raises the following puzzle for Bayesian Confirmation Theory discussed extensively by Glymour: Suppose that *E* is an evidentiary statement that has been known for some time -- that is, that it is *old evidence*; and suppose that *H* is a scientific theory that has been under consideration for some time. One day it is discovered that *H* implies *E*. In scientific practice, the discovery that *H* implied *E* would typically be taken to provide some degree of confirmatory support for *H*. But Bayesian Confirmation Theory seems unable to explain how a previously known evidentiary statement *E* could provide any new support for H. For conditionalization to come into play, there must be a change in the probability of the evidence statement *E*. Where *E* is old evidence, there is no change in its probability. Some Bayesians who have tried to solve this problem (e.g., Garber) have typically tried to weaken the logical omniscience assumption to allow for the possibility of discovering logical relations (e.g., that *H* and suitable auxiliary assumptions imply *E*). As mentioned above, relaxing the logical omniscience assumption threatens to block the derivation of almost all of the important results in Bayesian epistemology, so there is no general agreement among Bayesians on how to solve this problem. Other Bayesians (e.g., Lange) employ the Bayesian formalism as a tool in the *rational reconstruction* of the evidentiary support for a scientific hypothesis, where it is irrelevant to the rational reconstruction whether the evidence was discovered before or after the theory was initially formulated.

C. The problem of rigid conditional probabilities. When one conditionalizes, one applies the initial conditional probabilities to determine final unconditional probabilities. Throughout, the conditional probabilities themselves do not change; they remain rigid. Examples of the Problem of Old Evidence are but one of a variety of cases in which it seems that it can be rational to change one's initial conditional probabilities. Thus, many Bayesians reject the Simple Principle of Conditionalization in favor of a qualified principle, limited to situations in which one does not change one's initial conditional probabilities. There is no generally accepted account of when it is rational to maintain rigid initial conditional probabilities and when it is not.

D. The problem of prediction vs. accommodation. Related to the problem of Old Evidence is the following potential problem: Consider two different scenarios. In the first, theory *H* was developed in part to *accommodate* (i.e., to imply) some previously known evidence E. In the second, theory *H* was developed at a time when *E* was not known. It was because *E* was derived as a *prediction* from *H* that a test was performed and *E* was found to be true. It seems that E's being true would provide a greater degree of confirmation for *H* if the truth of *E* had been *predicted* by *H* than if *H* had been developed to *accommodate* the truth of *E*. There is no general agreement among Bayesians about how to resolve this problem. Some (e.g., Horwich) argue that Bayesianism implies that there is no important difference between prediction and accommodation, and try to defend that implication. Others (e.g., Maher) argue that there is a way to understand Bayesianism so as to explain why there is an important difference between prediction and accommodation.

E. The problem of new theories. Suppose that there is one theory H_1 that is generally regarded as highly confirmed by the available evidence *E*. It is possible that simply the introduction of an alternative theory H_2 can lead to an erosion of H_1's support. It is plausible to think that Copernicus' introduction of the heliocentric hypothesis had this effect on the previously unchallenged Ptolemaic earth-centered astronomy. This sort of change cannot be explained by conditionalization. It is for this reason that many Bayesians prefer to focus on probability ratios of hypotheses (see the Ratio Formula above), rather than their absolute probability; but it is clear that the introduction of a new theory could also alter the probability ratio of two hypotheses -- for example, if it implied one of them as a special case.

6. Other Principles of Bayesian Epistemology

Other principles of Bayesian epistemology have been proposed, but none has garnered anywhere near a majority of support among Bayesians. The most important proposals are merely mentioned here. It is beyond the scope of this entry to discuss them in any detail.

A. Other principles of synchronic coherence. Are the probability laws the only standards of synchronic coherence for degrees of belief? Van Fraassen has proposed an additional principle (Reflection or Special Reflection), which he now regards as a special case of an even more general principle (General Reflection).[3]

B. Other probabilistic rules of inference. There seem to be at least two different concepts of probability: the probability that is involved in degrees of belief (epistemic or subjective probability) and the probability that is involved in random events, such as the tossing of a coin (chance). De Finetti thought this was a mistake and that there was only one kind of probability, subjective probability. For Bayesians who believe in both kinds of probability, an important question is: What is (or should be) the relation between them? The answer can be found in the various proposals for principles of direct inference in the literature. Typically, principles of direct inference are proposed as principles for inferring subjective or epistemic probabilities from beliefs about objective chance (e.g., Pollock). Lewis reverses the direction of inference, and proposes to infer beliefs about objective chance from subjective or epistemic probabilities, via his (Reformulated) Principal Principle.[4]

C. Principles of rational acceptance. What is the relation between beliefs and degrees of belief? Jeffrey proposes to give up the notion of belief (at least for empirical statements) and make do with only degrees of belief. Other authors (e.g., Levi, Maher, Kaplan) propose principles of rational acceptance as part of accounts of when it is rational to accept a statement as true, not merely to regard it as probable.

Probability Laws

There are many different versions of the probability laws. Probability can be defined over sentences or over sets; it can be defined as conditional or unconditional. This article assumes the following laws of unconditional probability defined over sentences:

> (A1) All probabilities are between zero and one -- that is, for any sentence S: $0 \leq P(S) \leq 1$.
>
> (A2) Logical truths have probability one -- that is, for any logical truth L: $P(L) = 1$.
>
> (A3) Where S and T, are mutually exclusive, the probability of S or T ($S \vee T$) is the sum of their individual probabilities -- that is: $P(S \vee T) = P(S) + P(T)$.

Using these laws, it is possible to derive as theorems many of the standards truths of probability -- for example, that the probability of a sentence and its negation sum to one -- in other words: $P(\sim S) = 1 - P(S)$.

(A3) is referred to as the *Principle of Finite Additivity*, because it involves only finite sums. Most mathematical treatments of probability require an extension of (A3) to cover countably infinite sums. The result is a *Principle of Countable Additivity*. The standard way of stating this axiom involves translating the axioms into set theory, where countably infinite unions (corresponding to infinite disjunctions) are defined. The relation to (A3) is clearer if one simply extends the ordinary notion of sentence to include infinitely long expressions formed in accordance with the formation rules of the language -- thus allowing for the possibility of infinite disjunctions:

> (A4) Where S_1, S_2, ... is a countably infinite sequence of mutually exclusive sentences: $P(S_1 \vee S_2 \vee \dots) = P(S_1) + P(S_2) + \dots$.

The discussion of the probability axioms in the text assumes only Finite Additivity, because it is only Axioms (A1)-(A3) that can be given a Dutch Book justification.

Notes to Bayesian Epistemology

Notes

1. Some authors (e.g., de Finetti) take conditional probabilities rather than unconditional probabilities as primitive. Following ideas of Popper and Réyni, it is possible to take unconditional probabilities as primitive and define conditional probabilities for statements with prior probability of zero.

2. The assumptions are those necessary to assure that gambles are ranked by their expected monetary value. The idea of explaining rational behavior in terms of maximizing the expected value of gambles led to the 20th century development of Bayesian Decision Theory. See, for example, Ramsey, de Finetti, Savage, and Jeffrey.

3. Van Fraasen's Special Reflection Principle is: $P(A|p_t(A) = x) = x$ (where $t \geq 0$). His General Reflection Principle is that one's current opinion about an event E must lie in the range spanned by the possible opinions (based on one's present opinion) that one may come to have about E at later time t. Van Fraassen provides diachronic Dutch Book Arguments for both, though he downplays the significance of Dutch Book Arguments generally.

4. Lewis's (Reformulated) Principal Principle relates Chance for a world w at time t (P_{tw}) to Credence (C) as a function of the complete history of world w up to time t (H_{tw}) and the complete theory of chance for world w (T_w) as follows: $P_{tw}(A) = C(A/H_{tw}T_w)$.

Dutch Book Arguments

The Ramsey/de Finetti argument can be illustrated by an example. Suppose that agent *A*'s degrees of belief in *S* and ~*S* (written *db*(*S*) and *db*(~*S*)) are each .51, and, thus that their sum 1.02 (greater than one). On the behavioral interpretation of degrees of belief introduced above, *A* would be willing to pay *db*(*S*) × $1 for a unit wager on *S* and *db*(~*S*) × $1 for a unit wager on ~*S*. If a bookie *B* sells both wagers to *A* for a total of $1.02, the combination would be a synchronic Dutch Book -- synchronic because the wagers could both be entered into at the same time, and a Dutch Book because *A* would have paid $1.02 on a combination of wagers guaranteed to pay exactly $1. Thus, *A* would have a guaranteed net loss of $.02

The Lewis/Teller argument can also be illustrated by an example. Suppose that agent *A*'s degrees of belief satisfy the synchronic probabilistic coherence conditions -- that is, the probability laws. Suppose also that *A* has the following initial probabilities:

$P_i(S) = 1/5$

$P_i(T) = 1/5$

$P_i(S\&T) = 1/10$

$P_i(S/T) = 1/2$

A is about to learn whether or not *T* is true (nothing more). If *A* learns that *T* is true, the Simple Principle of Conditionalization would require *A* to change her probability assignment to *S* ($P_f(S)$) to equal $P_i(S/T)$ = ½. Suppose *A* realizes that, if she learns that *T* is true, she will change her probability assignment to *S* to $P_f(S) = 6/10 > P_i(S/T)$ [a parallel argument applies to the case in which *A* knows in advance that were she to learn that *T*, $P_f(S)$ would be less than $P_i(S/T)$].

Initially, bookie *B* can make the following wagers with *A*:

(1) *B* sells *A* an unconditional wager that pays $.10 if *T* is true for $P_i(T)$ × $.10 = 1/5 × $.10 = $.02.

(2) *B* buys from *A* a unit wager on *S* conditional on *T* for $P_i(S/T) \times \$1 = ½ \times \$1 = \$.50$.

After it is determined whether or not *T* is true, there are two possibilities:

(a) *T* is not true.

In that case, *A* loses $.02 on the first wager and the second wager is called off, so no one wins or loses anything on the second wager. The result is a net loss of $.02 for *A*.

(b) *T* is true.

In that case, *B* makes an additional wager with *A*:

(3) *B* sells to *A* an unconditional unit wager on *S* for $P_f(S) \times \$1 = 6/10 \times \$1 = \$.60$.

Then there are two further sub-possibilities:

(b1) *S* is true. *A* gains $.08 on wager 1 (the $.10 pay-off, less the $.02 that *A* paid for the wager); *A* loses $.50 on wager 2 (*B* paid *A* $.50 for the wager, but *A* must pay $1 to *B*); *A* gains $.40 on wager 3 (*A* paid *B* $.60 for the wager, but *B* must pay *A* $1). The net result of all three wagers is a $.02 loss for *A*.

(b2) *S* is not true. Again *A* gains $.08 on wager 1 (the $.10 pay-off, less the $.02 that *A* paid for the wager); *A* gains $.50 on wager 2 (*B* paid *A* $.50 for the wager, and *A* does not pay *B* anything); *A* loses $.60 on wager 3 (*A* paid *B* $.60 for the wager, and *B* does not pay *A* anything). Again the net result of all three wagers is a $.02 loss for *A*.

Because (a), (b1), and (b2) exhaust all the logical possibilities, the example is one in which *A* is guaranteed to lose $.02, no matter what happens. Because wager 3 cannot be made at the same time as wagers 1 and 2, the combination of wagers 1-3 is a diachronic Dutch Book.

Scottish Philosophy in the Nineteenth Century

Philosophical debate in 19th century Scotland was very vigorous, its agenda being set in large part by the impact of Kant and German Idealism on the philosophical tradition of the Scottish Enlightenment. The principal figures are Sir William Hamilton, James Frederick Ferrier and Alexander Bain, and later in the century, the so-called ‘Glasgow Idealists’ notably Edward Caird and Sir Henry Jones.

1. The Enlightenment Background

While Scottish philosophy of the 18th century is studied extensively, Scottish philosophy in the 19th century is neglected to the point of being virtually unknown. Francis Hutcheson, David Hume and Thomas Reid and are names familiar to almost all philosophers; Sir William Hamilton, James Frederick Ferrier and Alexander Bain to hardly any. Yet in their day, the names of these philosophers were not only prominent in Scotland, but widely known across Europe. To understand this decline in reputation, it is necessary to see 19th century Scottish philosophy against the background of the century that preceded it.

According to George Davie there is an

> opposition … between … two contrasting positions that in their tension provided Scottish philosophy with its central problem: the Berkeleian system, according to which, in the interests of reconciling progress with traditional standards, we are to set aside the instincts

> of the farmer in favour of the sophistication of the philosopher and to think with the learned while we talk with the vulgar; and the Hutchesonian system, according to which, with the same aim of reconciling material advance with the intellectual principle, we are to respect the instincts of the farmer as against the sophistication of the philosopher and initiate a sort of dialogue between the vulgar and the learned, instead of talking down to the farmer from the standpoint of the philosopher. (Davie 1994: 41-2)

Cast in these terms it is easy to place the two most famous philosophers of the Scottish Enlightenment on either side of the divide. On the side of the first is Hume, whose skeptical conclusions arise from the Berkleyan presupposition asserted in the very first sentence of his *Treatise of Human Nature*

> All the perceptions of the human mind resolve themselves into two distinct kinds, which I shall call IMPRESSIONS and IDEAS. The difference betwixt these consists in the degrees of force and liveliness with which they strike upon the mind. (Hume 1888: 1)

On the other side is Thomas Reid, for whom the errors of Hume result from the boldness of his starting point.

> It is genius, and not the want of it, that adulterates philosophy, and fills it with error and false theory. A creative imagination disdains the mean offices of digging for a foundation, of removing rubbish, and carrying materials: leaving these servile employments to the drudges in science, it plans a design, and raises a fabric. (Reid 1997: 15)

The problem as Reid saw it was that a highly theoretical philosophy was trying to run before it could walk, because in sharp contrast to subjects that are "really sciences" -- mechanics, astronomy and optics are the examples he gives --

> when we turn our attention inward and consider the phaenomena of human thoughts, opinions and perceptions, and endeavour to trace them to the general laws and first principles of our constitution, we are immediately involved in darkness and perplexity. And if common sense, or the principles of education, happen not to be stubborn, it is odds but we end in absolute skepticism. (Reid 1997: 16)

It is well known that, on Reid's analysis, Hume's skepticism derives in large part from his implicit subscription to the 'way of ideas', a conception of knowledge and experience that finds its origins in Descartes, Malebranche and Locke, and its most dramatic exposition in Berkeley who, though no skeptic, "proved by unanswerable arguments what no man in his senses could believe" (Reid 1997: 20). The antidote to such skepticism is common sense, but not of the robust sort displayed by Dr Johnson when he purported to refute Berkeley by kicking a stone. 'Common sense' can mean two things, in fact: widespread popular conviction on the one hand, or the basic principles at work in human reasoning and belief formation on the other. Widespread conviction can be false, of course, which is why the method of the School of Common Sense was thought suspect by many, described by Kant, for example, as a

stratagem by which 'the stalest windbag can confidently take up with the soundest thinker" (Kant 1951: 259). But in Reid at any rate, philosophical inquiry into the human mind is not a matter of making popular opinion the test of truth, but of initiating a 'dialogue between the vulgar and the learned,' (to repeat Davie's happy phrase) in which proper weight is attached to actual minds at work.

There is, then, this deep division within the philosophy of the Scottish Enlightenment, yet it occurs within a context of striking unanimity also. "Wise men now agree, or ought to agree in this, that there is but one way to the knowledge of nature's works; the way of observation and experiment" Reid writes (Reid 1997: 11), thereby endorsing the express intention of Hume to "introduce the experimental method of reasoning into moral subjects' (the subtitle of the *Treatise*). Both remarks reflect a commitment to the project of a 'science of mind', a project common to all the major Scottish philosophers of the period. Thus George Turnbull (Reid's teacher) writing in 1740 says "I was led long ago to apply myself to the study of the human mind in the same way as to that of the human body" (quoted in Davie 1994: 24)

In short, both division and unanimity are present within eighteenth century Scottish philosophy, unanimity with respect to aim – a science of mind – and division with respect to method – the 'principles of common sense' versus 'the way of ideas'. This is a tension, however, within only one part of 18th century Scottish philosophy, namely the philosophy of sensation and perception, and not perhaps the most influential part. The Scottish Enlightenment is in many ways more marked by the type of thinking about social and political topics that we find in Adam Smith and Adam Ferguson, as well as Hume, who in this respect take their cue from Hutcheson. The example *par excellence* is Smith's *Theory of Moral Sentiments*(1759; 6th edition 1790), where the Humean ambition of countering the "books of divinity and abstruse metaphysics" (*Treatise*) was further by a sympathetic attention to how human beings in society actually are, and what social forms and political arrangements will best work to their happiness and well being.

In the 19th century, this strand of Enlightenment thinking ceased to be an important part of the philosophical agenda. That agenda was dominated, rather, by the 'science of mind' more narrowly conceived, that is to say logic (i.e the philosophy of truth and reason) and the philosophy of perception. Consequently, from 1810 onwards, when Thomas Brown (1778-1820) took up the Chair of Moral Philosophy at Edinburgh, the story of Scottish philosophy is that of repeated attempts to resolve the tension that lay within that 'science'. It is also a story of remarkable continuity. Brown (1778-1820) was a student of Dugald Stewart (1753-1828), who in turn was a student and friend of Reid and himself held the Chair of Moral Philosophy at both Glasgow and Edinburgh. Stewart was enormously highly thought of in his own day, but in retrospect his contribution to the central debate in Scottish philosophy is limited. Brown died prematurely, but he was a prolific writer from an early age and left behind voluminous lectures. These lectures are critical of Reid (though on certain issues Brown way be said to side with Reid against Hume). On publication they were widely and rapturously received, but fell into almost total neglect by 1840. Perhaps their most enduring effect on the debate arose from the re-interpretation and defence of Reid that they induced on the part of the most prominent philosopher of the period – Sir William Hamilton.

2. Sir William Hamilton (1788-1856)

Sir William Hamilton was a graduate of the Universities of Glasgow and Oxford. At Glasgow he studied logic and moral philosophy under George Jardine and James Mylne both of whom are figures included in James McCosh's *The Scottish Philosophy*. In 1807 at Balliol College Oxford he held the Snell Exhibition, a scholarship that regularly allowed Scottish students of philosophy to spend time at England's oldest university, and he gained an extensive knowledge of Aristotelianism there. From 1811-21 he worked at the Scottish Bar (not altogether successfully) until being appointed Professor of Universal and Civil History at the University of Edinburgh, where he transferred to the Chair of Logic and Metaphysics in 1836, a post he held until his death in 1856.

At the height of his powers, Hamilton was regarded as a major European intellectual figure, and evidence of his stature lies in the fact that Hamilton was included in the series *Philosophical Classics*, edited by William Knight, Professor of Moral Philosophy at St Andrews, and thus ranked alongside Descartes, Berkeley, Locke, Kant and Hegel. Such an estimation must now strike us as bizarre, yet there is point in asking why his times regarded him in such a favorable light. The answer is that, thanks to two trips he made to Germany during his years as a lawyer, Hamilton acquired an extensive knowledge of German philosophy, little of which had been translated into English and which he could read in the original language. At the same time, he was not only thoroughly versed in the Scottish tradition of philosophy that he had acquired from Jardine and Mill, but an enthusiastic exponent of Reid, whose collected works he edited and annotated extensively. He was thus perfectly placed to broaden the horizons of Scottish philosophy, to push it beyond the narrower confines of Common Sense by bringing to wider attention the importance of Kant, and yet to do so as one profoundly sympathetic to the native tradition. It is precisely for these reasons, in fact, that he is praised by John Veitch in the *Philosophical Classics* volume devoted to his philosophy.

Hamilton's writings are extensive but arguably his views can be adequately ascertained from three long essays which appeared in the *Edinburgh Review* -- 'The Philosophy of the Unconditioned' (1829), 'The Philosophy of Perception' (1830) and 'Logic' (1833), subsequently republished in a collection of his writings. In the first of these Hamilton recounts the course philosophy had taken in France after "the philosophy of Descartes and Malebranche had sunk into oblivion"(Hamilton 1853: 2). At first there emerged a highly materialist version of Lockean empiricism "a doctrine so melancholy in its consequences, and founded on principles thus partial and exaggerated, [that it] could not be permanent" (*ibid*., 3). Rescue came from two sources. The first of these was the Scottish Philosophy of Common Sense which showed that there are mental phenomena that cannot be interpreted as any form of sensation and that " intelligence supposed principles, which, as *conditions* of its activity, cannot be the *results* of its operation" (*ibid*., 3). The other source of renewal was German philosophy after Kant, and in particular the Absolute Idealism that was "founded by Fichte, but evolved by Schelling" (*ibid*., 6). 'The Philosophy of the Unconditioned' is an examination of the most prominent French philosopher to make use of this second source – Victor Cousin – but this provides an occasion for Hamilton to formulate his own solution to the tension between the philosophy of common sense and the way of ideas.

The question at issue can be expressed in a number of different ways. Kant held that we can only have knowledge of phenomena, never of noumena or things in themselves. Clearly this version of phenomenalism, though in many ways the antithesis of empiricism, has elements in common with the 'way of ideas' to which Reid objected, which holds that the mind apprehends the world indirectly, through 'impressions'. The alternative position, referred to in the 19thcentury as 'presentationism' is often called 'direct realism' and holds, as Reid contends, that we directly apprehend the world of real things. Both positions have their difficulties. Those who followed Kant, notably Fichte and Schelling, sought to escape the 'scandal' of unknowable things-in-themselves, and those who followed Reid sought to overcome the contention implicit in his approach that our knowledge of the world is 'conditioned' by the principle of common sense. Hence the pursuit of a philosophy of the 'unconditioned'.

Hamilton's solution, ultimately, is to combine phenomenalism and presentationism. In 'The Philosophy of Perception' he engages in the debate by defending Reid against the criticism brought against him in Thomas Brown's postumously published *Lectures*, and in a very vigorous manner – "It is always unlucky to stumble on the threshold. The paragraph (Lect.xxvii) in which Dr Brown opens his attack on Reid contains more mistakes than sentences" (*ibid*., 69). Brown claimed that a close analysis of Reid's writings showed that his position on perception was not really that of direct realism but "hypothetical realism", that is the belief in an external world that cannot be known directly. It is this contention that Hamilton aims to refute, but it is arguable that he misinterprets Brown. Moreover in his notes to Reid's *Collected Works*, which were composed rather later, he appears to come round to something very like Brown's interpretation and to hold that Reid was not, strictly speaking, a direct realist after all.

If we construe Reid as holding that in the act of perception there are three elements – the physiological modification of the organ, a mental sensation and the perception of an object – then we can contrast this with Hamilton's position which holds that the mental sensation and the perception are simultaneous and in a sense two sides of the same coin. Reid holds, of course, that we do not reason from sensation to perception; the apprehending mind moves from one to the other by a natural, inbuilt instinct – one of the principles of common sense. Hamilton too holds that there is no reasoning process here, but he also thinks that the continuing division that Reid is employing between sensation and perception is incompatible with the idea of immediate perception or direct realism between. Hence his amendment, which so to speak ties the sensation and perception together. But how is this further contention to be sustained? Is it a conceptual truth of some kind, or an empirical observation about how the mind works? Hamilton's writings in general tend to assertion more than argument, and while he has a great deal to say on this point, it does seem that his 'solution' to the problem of perception is a an arbitrary stipulation designed to overcome it. At any rate, if we do press the question of its defence, we quickly encounter a new version of the old division, namely whether the perception is to be identified as a manifestation of self-evident principles of common sense, or as a psychological association of ideas. In this sense Hamilton's thesis is still set within the fundamental parameters of the Hume/Reid debate. It was the next major figure in 19th century Scottish philosophy – Hamilton's student and friend James Frederick Ferrier – who made the most strenuous effort to take a different tack.

3. James Frederick Ferrier (1808-1864)

It is a notable fact that the identification of 'Scottish philosophy' with 'Common Sense' is not one that the 18th century philosophers themselves made. Indeed, it was only in the 19th century that something called 'Scottish philosophy' came to self-consciousness, and only then that books with 'Scottish philosophy' in their titles began to appear. The most famous of these was James McCosh's encyclopaedic *The Scottish Philosophy* (1875), and perhaps the most insightful *Scottish Philosophy* (1885) by Andrew Seth Pringle Pattison But from the point of view of the century's principle philosophical debate, the most interesting is J F Ferrier's *Scottish Philosophy, the Old and the New*, (1854). This is because it was expressly written in defence of the contention that it is possible to engage in something called 'Scottish philosophy' while departing radically from the tenets of Reid, Stewart and so on. Ferrier writes with great force and feeling.

> It has been asserted, that my philosophy is of Germanic origin and complexion. A broader fabrication than that never dropped from human lips or dribbled from the point of a pen. My philosophy is Scottish to the very core; it is national in every fibre and articulation of its frame. It is a natural growth of old Scotland's soil and has drunk in no nourishment from any other land. Are we to judge the productions of Scotland by merely looking to what Scotland has hitherto produced? May a philosopher not be, heart and soul, a Scotsman – may he not be a Scotsman in all his intellectual movements, even though he should have the misfortune to differ in certain respects, from Dr Reid and Sir William Hamilton (Ferrier 1854: 12)

The explanation of the feeling with which Ferrier writes lies in the fact his little book is a response to the charge levelled against him in the contest for the Chair of Moral Philosophy at Edinburgh (then still in the gift of the Town Council), when he was accused by the Free Church party of departing from 'the Scottish philosophy' in favour of some sort of Hegelianism. This charge was almost certainly motivated by the ecclesiastical rivalries generated by the Disruption in the Church of Scotland that took place in 1843, but it is nonetheless true that Ferrier expressly denounces a certain conception of 'Common Sense' philosophy, and one which he identifies closely with Reid. Indeed he is not afraid to repeat his objections in his defence of himself.

> Suppose we are discussing the subject of salt, and that we say 'salt is white and gritty, it is in some degree moist, it is sometimes put into a salt cellar and placed on the dinner table …' … No man would be considered much of a chemist, who was merely acquainted with these and other such circumstances, concerning salt … . So, in philosophy, no man can be called a philosopher who merely knows and says, that he and other people exist, that there is an external world, that a man is the same to day as he was yesterday, and so forth. These are undoubtedly truths, but I maintain that they are not truths in philosophy, any more than those just mentioned are truths in chemistry. Our old Scottish school, however, is of a different way of thinking. It represents these and similar facts as the first truths of philosophy, and to these it has recourse in handling the deeper questions of metaphysics. I have no objections to this, for those who like it -- only my system deals with first truths of a very different order; and it denies that the first truths of the old Scottish school are truths

> in philosophy at all. This is one very fundamental point of difference between the old and the new Scottish system of metaphysics (*ibid*., 7)

It is important to note that Ferrier thinks this castigation of one version of ‘Common Sense’ philosophy is quite compatible with claiming the right to be the inheritor of, though not restricted by, the programme of Reid and Hamilton. And there are indeed several points of contact to be observed. The first is this. Ferrier shares with the school of Reid and Hamilton an almost unspoken assumption that the question of mind and world lies at the heart of philosophy. In this they all differ from the alternative conception of moral philosophy as social inquiry, which as we have already noted, is to be found in Ferguson, parts of Hume, and above all Adam Smith. Second, and more importantly perhaps, Ferrier’s own philosophical reflections continue to fit Davies description of Scottish philosophy as a ‘dialogue between the vulgar and the learned’.

Ferrier’s reputation rested upon an earlier series of essays on *The Philosophy of Consciousness* which appeared in Blackwood’s Magazine between 1838 and 1843. In these essays he took his stand on the contention that consciousness implies the impossibility of a naturalistic science of mind, and in a later essay robustly defends a version of Berkeleyan idealism. While Reid thought that Berkeley’s philosophical position was one that "no man in his senses could believe", somewhat surprisingly perhaps, Ferrier describes Berkeley as "the champion of common sense . . . who could have foiled the prince of skeptics at his own weapons" (Ferrier 1865: 301). "Among all philosophers ancient or modern, we are acquainted with none who presents fewer vulnerable points that Bishop Berkeley. His language it is true, has sometimes the appearance of paradox; but there is nothing paradoxical in his thoughts, and time has proved the adamantine solidity of his principles." (*ibid*., p.291) By Ferrier’s account Berkeley settles the issue of sensation and perception with which Hamilton struggled, by seeing that there is a false abstraction here.

> The external world *in itself*, and the external world in relation *to us*, was a philosophic distinction which he [Berkeley] refused to recognize. In his creed, the substantive and phenomenal were one. And though he has been accused of sacrificing the substance to the shadow, and though he still continues to be charged, by every philosophical writer, with reducing all things to ideas in the mind, he was guilty of no such absurdity … There does not appear to be much justice in the ordinary allegation, that Berkeley discredited the testimony of the senses, and denied the existence of the material universe. He merely denied the distinction between things and their appearances, and maintained that the thing *was* the appearance and the appearance *was* the thing. (*ibid*., 302-3)

On this interpretation Berkeley espouses a sort of idealism but

> genuine idealism, looking only to the fact, and instructed by the unadulterated dictates of common sense, denies … that we can separate in thought objects and perceptions *at all*; hence this system has nothing whatever to do either with the preservation or the destruction of the material universe; and hence, too, it is identical … with genuine

unperverted realism. (*ibid*., 309)

In this way Ferrier, despite his disagreements, actually concurs with Reid's strictures on the kind of philosophical theorizing that tries to deploy Newtonian methods in the way that Hume does. Indeed, Ferrier thinks that "the inert and lifeless character of modern philosophy is ultimately attributable to her having degenerated into a physical science" (*ibid*., 191), and he condemns the resulting "picture of man" as "a wretched association machine, through which ideas pass linked only by laws over which the machine has no control" (*ibid*., 196). His alternative to this externalist conception of 'the science of mind' is a return to the introspective examination of human consciousness. "Consciousness is philosophy nascent; philosophy is consciousness in full bloom and blow. The difference between them is only one of degree, and not one of kind; and thus all conscious men are to a certain extent philosophers, although they may not know it" (*ibid*., 197) In short, the proper engagement of philosophy is a matter of bringing consciousness to a better understanding of itself, which is at least one interpretation of the ambition of Reid's *Inquiry*.

Ferrier's philosophy, then, constitutes a further excursion in the common sense tradition, but one which sets itself at some considerable distance from Reid. For Reid, Berkeley is one of the chief architects of 'the way of ideas', and hence though not himself a skeptic, the purveyor of a philosophy that makes radical skepticism inevitable. In sharp contrast, for Ferrier, Berkeley's philosophy (with some additions of Ferrier's own) is the *answer*to skepticism. It hardly needs to be said that this was a highly controversial position. Moreover, it throws the whole subject of mind and consciousness back into the realms of metaphysical philosophy and hence seems to abandon the shared methodological assumption that, to quote Reid again, "there is but one way to the knowledge of nature's works; the way of observation and experiment" a supposition he wholeheartedly shared with Hume. This implication – that the methods of the sciences inapplicable to philosophy -- somewhat isolated Ferrier within Scottish philosophy. Though he was regarded with great acclaim in continental Europe, Scottish philosophers moved in different directions, some to an intensification of the experimental method, and some to Absolute Idealism. Of the first group, the most prominent and influential was Alexander Bain.

4. Alexander Bain (1818-1903)

Alexander Bain was Regius Professor of Logic at the University of Aberdeen from 1860 to 1880. A man of remarkable gifts, he was appointed to the Chair largely on the strength of distinguished philosophical work he had published while working as a journalist in London. *Dissertations on Leading Philosophical Question*s(1903), is a collection of his essays published in retirement, though almost all had originally appeared in the journal *Mind*, a journal he was instrumental in founding, In several of these essays, Bain takes Reid and Hamilton as his starting point and, broadly, follows the same methods. But he pushes them in a much more strongly empirical direction. The most interesting of his *Dissertations*, in this connection, is entitled 'Associationist Controversies' and at the heart of these controversies we can find a distinction between philosophy and psychology which both reveals the significant difference between Bain and Ferrier, and establishes the discipline of experimental psychology in its own right.

> We are, at the moment, in the midst of a conflict of views as to the priority of Metaphysics and Psychology. If indeed the two are closely identified as some suppose, there is no conflict; there is in fact, but one study. If, on the other hand, there are two subjects, each ought to be carried on apart for a certain length, before they can either confirm or weaken each other. I believe that in strictness, a disinterested Psychology should come first in order, and that, after going on a little way in amassing the facts, it should revise its fundamental assumptions … I do not see any mode of attaining a correct Metaphysics until Psychology has at least made some way upon a provisional Metaphysics (Bain 1903: 38)

Bain can be interpreted as a practitioner of the 'science of mind' no less than Reid or Hume. But whereas in Reid and Hume the distinction between philosophy and psychology as the modern world understands it, was unclear, it is one of Bain's chief claims to enduring significance that, as this quotation reveals, he brought the distinction between psychological and metaphysical questions to prominence, and in what we would call his research programme he gave priority to the former. The conclusion to be drawn is that Bain, like Ferrier, can be seen to stand in the tradition of Scottish philosophy in the sense that he adopted its methods. But in contrast to Ferrier, he did so in ways that further removed the question of sensation and perception from the realms of traditional metaphysics, and pressed the study of the mind in the direction of empirical psychology.

One notable feature of this development lies in the fact that Bain was one of the principal exponents and defenders of 'associationism', whose origins, arguably, are to be found most clearly in Hume's *Treatise*. Associationism is the application of empirical observation to the relation between ideas and experiences. What it seeks is observed regularities, in the hope of formulating psychological laws that will enable us to order the contents of mind. Two such principles -- Contiguity and Similarity -- were widely accepted, and identified by Bain as being employed by Reid and Hamilton. A third -- Contrast -- was more disputable, and in 'Associationist Controversies' Bain is principally concerned with the nature and identifiable independence of principles such as these.

However, for present purposes his arguments are interesting chiefly not so much for their elaboration of associationism, but for the light they throw on the development of Scottish philosophy in the nineteenth century. One point in particular seems to me illuminating. In the dispute between Reid and Hume with respect to the operations of the mind one of the fundamental points of difference is this. Reid is trying, in the main, to establish basic principles of the mind's operation which will vindicate its rationality, and hence avoid the depths of skepticism into which Hume's account forces it. Hume, on the contrary, declares that "reason is nothing but a wonderful and unintelligible instinct in our souls which carries us along a certain train of ideas … [and that this] habit is nothing but one of the principles of nature, and derives all its force from that origin" (Hume 1888 : 179), Reid's purpose is precisely to show that the basic operations of the mind are those of intelligibility. Now in terms of this difference, Bain is of Hume's persuasion. This is revealed not merely in his striking deployment of decidedly Humean terminology when, for instance, he contrasts the perception and the memory of a thing in terms of 'vividness' (Bain 1903: 42). It is even more evident when he asserts that "The flow of representations in dreaming and madness offers the best field of observation for the study of associations as such" (*ibid*., 45).

What this remark reveals is that Bain is interested first in establishing empirical laws with respect to the contents of the human mind. The reason that he thinks dreaming and madness are the best places to start is precisely because he sees that the pursuit of rational principles, that is to say, philosophically coherent principles, is likely to distort our observation by inclining us to see rational connections rather than empirical associations, or as he puts it "associations as such." In this respect he is employing Hume's rather than Reid's conception of human nature. Certainly he reserves judgement on the final outcome of these investigations with respect to philosophy, arguing only for the priority of psychology over metaphysics and not, as Hume may be said to do, for the elimination of the second by the first. But so far as the science of mind that had been such a marked feature of Scottish philosophy goes, Bain clearsightedly pursues its more empirical ambitions.

For Ferrier the empirical laws of association that Bain seeks are not 'truths in philosophy'. No one can be called a philosopher who merely knows and says, that in dreaming or madness this mental representation tends to be associated with that. The philosopher aspires, rather, to make sense of experience, and the whole point about the experience of the dreamer or the madman is that no sense is to be made of it. By contrast, the empirical psychologist, seriously committed to the experimental method, does not, in the end, render consciousness intelligible; he or she simply describes how the mind works.

With Ferrier and Bain, then, the tension within Scottish philosophy that Davie has identified is resolved in radically different ways, the first by a return to metaphysics, the second by an advance to psychology. Both can claim to be inheritors of the Scottish tradition, but both in their different ways may be said to have brought about its demise. With Bain, the nature of the demise is evident; the philosophy of mind is replaced by empirical psychology. With Ferrier, the nature of the demise is rather different. Faced with the prospect of returning to Berkeleyan metaphysics, several prominent Scottish philosophers preferred to look elsewhere, namely to Germany and Hegel. The result was that as the century ended a small group known as the Glasgow Idealists came to prominence.

5. The Scottish Idealists

In his illuminating study *Scottish Philosophy*, importantly subtitled *A comparison of the Scottish and German answers to Hume*, Andrew Seth Pringle Pattison remarks:

> The thread of national tradition, it is tolerably well known, has been but loosely held of late by many of our best Scottish students of philosophy. It will hardly be denied that the philosophical productions of the younger generation of our University men are more strongly impressed with a German than with a native stamp (Seth Pringle Pattison 1885:1-2)

Pringle Pattison does not say who it is he has in mind, but a knowledge of the period makes it relatively easy to guess. There is a danger, though, that the reference to Germany be somewhat misleading. An interest in, and a knowledge of, Kant can be found to go back to Hamilton, and far from being regarded

as a threat to the Scottish tradition was recognized (by Veitch, for instance) as an important part of its enrichment. The German philosophy referred to here, then, is that which emanated from Hegel.

The Secret of Hegel is the title of a very large book by James Hutchison Stirling, first published in 1864. Stirling is credited with bringing Hegel to the attention of British (and not just Scottish) philosophy for the first time, though a wit at the time remarked that if Stirling did know the secret of Hegel, he had kept it to himself! Though Stirling was, in modern terms, a layman (he held no university post) the book was well received, and it is a matter of some consequence that it contained significant criticism of Hamilton. In fact, Stirling subsequently published a short but highly critical volume entitled *Sir William Hamilton: being the philosophy of perception. An analysis* (1865). With these two books we can chart the diminishing interest in and influence of the Common Sense tradition within Scottish philosophy and the increasing influence of German Idealism and Hegel in particular.

Of the Scottish Idealists the most prominent and influential was unquestionably Edward Caird (1835-1908). A graduate of the University of Glasgow, after a period at Oxford he returned in 1866 to become Professor of Moral Philosophy at Glasgow, a post he held for almost 30 years, before returning to Oxford to become Master of Balliol. Caird was an admirer of Kant, who believed nevertheless that Kant had failed to capitalize fully on his own insights, and that the full import of his philosophy could be uncovered with the help of Hegel. The aim of philosophy, on this interpretation, was the ultimate reconciliation of seemingly incompatible elements in human experience – religion and science, freedom and causality, reason and desire, for instance. These things are made compatible by reconception, and what makes Caird’s view a version or application of Hegelianism is the idea that our knowledge of objects is perfected as we more adequately conceive of them as parts of a whole.

Caird has been generally regarded as a something of a fifth columnist as far as Scottish philosophy was concerned. George Davie describes him as "a very untypical Scotsman and one quite exceptionally apathetic to educational customs of the country" (Davie 1961: 86). However, this remark reflects the fact that over the course of the nineteenth century Scottish philosophers were concerned not only with philosophical debates of the kind reviewed here, but with the place of philosophy in the university curriculum. As a result, from Hamilton onwards, several of them wrote essays on educational reform and gave evidence to the many commissions of inquiry into the universities that were held. Caird’s indifference to the national tradition of philosophical education, if that is what it was, was simply the other side of his desire to bring Scottish philosophers into the wider context of contemporary European philosophy which was, of course, dominated by German Idealism. That he was neither alone nor unsuccessful in this ambition is evidenced by the fact that he inspired and recruited several other distinguished figures, most notably Sir Henry Jones, who also came to occupy the Chair of Moral Philosophy at Glasgow, and J H Muirhead, founder of the enduring Muirhead Library of Philosophy, a long series of major philosophical works published in London.

Nevertheless, it is true that between Caird and the Scottish (or Glasgow) Idealists on the one hand, and the tradition known as ‘The School of Common Sense’ there is such a marked difference, that the former can hardly be said to be a continuation of the latter, but rather to signal the end of a philosophical project

which had lasted the larger part of 200 years. The 19th century, in short, may be said to be the century in which a distinctively Scottish tradition in philosophy came to an end.

Robert Boyle

Boyle was one of a leading intellectual figures of the seventeenth century. He was a dedicated experimenter, unwilling to construct abstract theories to which his results had to conform. "Our Boyle," Oldenburg wrote to Spinoza, "is one of those who are distrustful enough of their reasoning to wish that the phenomena should agree with it" (Hall & Hall 1965-1977, 2:38). Boyle, though a champion of the corpuscularian doctrine, preferred simply to report the results of his experiments, including negative results, and frequently lamented the fact that we lacked "histories" (collections of experimental results and accurate observations) in various fields of scientific endeavour. He performed so many experiments that he was able, at one "time to loose … at once near five centuries of Experiments of my own" (BP 9:28). Nor was this an isolated loss; nonetheless the number, variety and scope of his experiments were such that he carried on working and publishing with no particular difficulty. "His books," as Huygens remarked to Leibniz immediately after Boyle’s death, "are full of experiments" (Huygens 1888, 10:239). Moreover, experiments were *exactly* what he was interested in, he had a certain missionary zeal in spreading the corpuscularian gospel, but he was not himself interested in detailed system building, a fact that was commonly noted. Leibniz told Huygens that he was "astonished" that Boyle "who has so many fine experiments, [had] not come to some theory of chemistry after meditating so long on them. Yet in his books, and for all the consequences that he draws from his observations, he concludes only what we all know, that everything happens mechanically. He is perhaps too reserved. Excellent men should leave us even their conjectures; they are wrong if they wish to give us only those truths that are certain" (Leibniz to Huygens, Dec. 29, 1691, in Huygens 1888, 10:228). Boyle was ahead of his time. In the next century d’Alembert wrote "the taste for systems … is today almost entirely banished from works of merit … a writer among us who praised systems would have come too late" (d’Alembert 1751, 94).[1]

Boyle was a corpuscularian, a term he employed to paper over the differences between believers in a vacuum, and believers in a plenum, given that both of them agreed that the explanation of natural occurrences should be solely in terms of particles of matter, their motion and interaction. Boyle consistently refused to pronounce on the question of whether these *minima naturalia* should be considered *atoms*, in the strict sense of that term, or not.

Even a metaphysical non-corpuscularian such as Leibniz agreed with Boyle in practical terms. "However much I agree with the Scholastics in this general and, so to speak, metaphysical explanation of the principles of bodies," he wrote to Arnauld in July 1686, "I am as corpuscular as one can be in the explanation of particular phenomena, and it is saying nothing to allege that they have forms or qualities" (Gerhardt 1875, 2:58, trans. Mason 1967).

Boyle's scientific range was wide. Besides his well known work in mechanics, medicine, hydrodynamics and a wide variety of experiments with his vacuum pump, he was interested both theoretically and practically in alchemy (see Principe 1998), where his interest seems to have been fueled more by his constant desire to acquire knowledge of God and the world than by any desire for riches. He "cultivated Chymistry with a disinterested mind," seeking the improvement of his own knowledge, "*the* gratifying the Curious & the Industrious; and *the* Acquist of some useful helps to make good & uncommon Medicins."[2] As a corpuscularian he believed that transmutation was physically possible. As a person he believed that it actually occurred. He believed that in his own laboratory gold had been transmuted into a "baser metal" with a specific gravity about two thirds of that of gold, and since he was, he said, more interested in the luciferous aspect of discovery than the lucriferous, he found the process equally interesting in either direction.[3]

During the course of his life he sought constantly to improve the lot of humanity. He was interested in the improvement of agricultural methods, in the possibility of extracting fresh water from salt, in the improvement of medicines and medicinal practice, in the possibility of preserving food by vacuum packing, and in a number of other useful results, actual or potential, of experimental philosophy. He viewed his theological interests and his work in natural philosophy as forming a seamless whole and constantly used results from the one area to enlighten matters in the other.

Convinced that Christianity was the religion instituted by God, Boyle was concerned that the Bible should be widely promulgated and he devoted time and energy to having it translated into a variety of languages such as Irish, Turkish, and various native American languages. He viewed such conversion attempts as being on all fours with his attempts to find more efficacious medicines for:

> To convert Infidels to the Christian Religion is a work of great Charity and kindnes to men. I. In regard of the evills it frees them from, such as, (1) the gross errors and prejudices they had entertain'd before they were instructed in it. (2ly) The vices and polutions they securely liv'd in, before they receiv'd the Gospel; *some* of which were unworthy of men as such; *others* very prejudicial to humane society's; and *others* very mischievous to the vicious persons themselves; and *others* <againe> great hinderances to the discovery and reception of usefull and noble truths. (3ly) The unexpressible Infelicitys that attend the greatest part of such Infidels & wicked Persons, in the future state.
>
> II. The Christian Religion brings mankind diverse positive Benefits, such as are, more cleare and extensive knowledg of God, and divine things; the Remission of Sins; the Favour of God; severall graces and vertues suitable to mens respective needs and conditions; and above all, a happy Immortality in the Life to come. (Boyle Papers [BP] 5:73-4)

---

1. Life[4]

Robert Boyle was born in Lismore, in Ireland, on the January 25, 1627. He was his parents' fourteenth, penultimate, child, and the last to survive to adulthood. Boyle was the youngest son and, after his sister Margaret died when he was 10, the youngest child of the family. Boyle speaks fondly of his parents, but he could not have known them well. His mother died in childbirth a few weeks after Boyle's third birthday, and he last saw his father just before he and his brother Francis left for a continental tour when Boyle was twelve.

Like many children Boyle had his share of near escapes from serious injury as a child, but the time and Boyle being what they were he saw in each of them the hand of God. Michael Hunter has pointed out that "the spiritual autobiography, aimed at chronicling God's purpose for the individual in question by recounting providential escapes, spiritual trials and conversion experiences," was "a characteristic genre of autobiographical writing in seventeenth-century England" (Hunter 1994a, xx), and Nicolas Canny notes that "The invocation of providence as an explanation for accidental or chance happenings in this life was so commonplace among sincere Protestants in the early seventeenth century that it had come to be considered irreverent or profane not so to attribute them" (Canny 1982, 28). But, though common enough, there is no doubt that, in Boyle's case at least, the protestations were sincere. He continued to believe in this divine attention, though in a more intellectual realm, throughout his life. In 1663 he wrote,

> And though I dare not affirm … that God discloses to Men the Great Mystery of Chymistry by Good Angels, or by Nocturnal Visions … yet perswaded I am, that the favor of God does (much more than most Men are aware of) vouchsafe to promote some Mens Proficiency in the study of Nature (Boyle Works [BW], 3:276, Birch 1772, II:61).[5]

In Geneva on his continental tour Boyle underwent what he clearly felt to be a conversion from nominal or at least unthinking Christianity to committed Christianity. One summer night, he "was suddenly waked in a Fright with such loud Claps of Thunder … & every clap … both preceded & attended with Flashes of lightning so numerous … & so dazling, that [he] began to imagine … the Day of Judgment's being come." This led him to vow that "all further additions to his life shud be more Religiously & carefully employ'd." Realizing the inefficacy of a promise exacted under duress, Boyle repeated the performance under a serene and cloudless sky "so solemnly that from that Day he dated his Conversion; renewing now

he was past Danger, the vow he had made whilst he fancy'd himselfe to be in it: that tho his Feare was (& he blush't it was so) the … occasion of his Resolution of Amendment; yet at least he might not owe his more deliberate consecration … of himselfe to Piety, to any less noble Motive then that of it's owne Excellence" (BP 37:181r-v).

The promise seems never to have been broken, and indeed the later Boyle stressed the need to have an *examined* faith. He pointed out that "usually, such as are born in such a place, espouse the opinions true or false, that obtain there" (BW, 12:421, Birch 1772, VI:712), indeed, "the greatest number of those that pass for Christians, profess themselves such only because Christianity is the religion of their Parents, or their Country, or their Prince, or those that have been, or may be, their Benefactors; which is in effect to say, that they are Christians, but upon the same grounds that would have made them Mahometans, if they had been born and bred in Turky" (BP 7:233). Boyle felt that more was required of the thinking believer. Locke agreed: often a child's notion of God does more "resemble the Opinion, and Notion of the Teacher, than represent the True God" (Essay, 1.14.13).

Hard on the heels of Boyle's enlightenment, doubts about his faith began to trouble him,[6] and these "distracting Doubts of some of the Fundamentals of Christianity" continued: "never after did these fleeting Clouds, cease now & then to darken … the clearest serenity of his quiet: which made him often say that Injections of this Nature were such a Disease to his Faith as the Tooth-ach is to the Body; for tho it be not mortall, 'tis very troublesome" (BP 37:182r).

Leaving Switzerland, Boyle, along with Marcombes and his brother crossed the Alps and entered Italy in September 1641 where, in Florence, he spent the winter. "In *Italy* he read over the lives of the ancient philosophers with the utmost attention," presumably in Diogenes Laertius, and "[t]he sect, which then struck him most, was that of the Stoics; and he tried his proficiency in their philosophy, by enduring a long fit of the tooth-ach with great unconcernedness."[7] Still in Italy he had (in the winter of 41-42) what seems to have been one of the very few sexual encounters of his life. Writing about himself in the third person as Philaretus (sometimes P., or Filaretus) he says:

> Nor did he sometimes scruple, in his Governor's Company, to visit the famousest Bordellos; whither resorting out of bare Curiosity, he retain'd there an unblemish't Chastity, & still return'd thence as honest as he went thither. Professing that he never found any such sermons against them, as they were against themselves. The Impudent Nakednesse of vice, clothing it with a Difformity, Description cannot reach, & the worst of Epithetes cannot but flatter. But tho P. were noe Fewell for forbidden Flames, he prov'd the Object of unnaturall ones. For being at that Time not above 15, & the Cares of the World having not yet faded a Complexion naturally fresh enuf; as he was once unaccompany'd diverting himselfe abroad, he was somewhat rudely presst by the Preposterous Courtship of 2 of those Fryers, whose Lust makes no distinction of Sexes; but that which it's Preference of their owne creates; & not without Difficulty, & Danger, forc't a scape from these gown'd Sodomites. Whose Goatish Heates, serv'd not a little to arme Filaretus against such Peoples specious Hyprocrisy; & heightn'd & fortify'd in him an Aversenesse for Opinions, which now the Religieux discredit as well as the Religion (BP

> 37:184r-v).

Leaving Italy Marcombes and the two boys found on arrival in Marseilles that the monies the Great Earl had been in the habit of sending were no longer to arrive and that, indeed, the last quarter's payment had been held up by Cork's London agent. Moreover, there was a letter from the Earl, unaware of the mischance affecting the quarterly payment, telling them that, as a result of the rebellion in Ireland, no more money was to be forthcoming: in the "dangerous and poore estate whereunto by gods providence" he had been reduced, he had "with much difficulty gott together two hundred and fifty pounds by selling of plate," but to pay Marcombes' bills punctually as he had in the past "I am noe waies able." So he advised Marcombes to use the money to bring the two boys

> out of some meet port in France to land either at dublin, Corke, or Youghall, (for all other Cities and Sea townes are possessed by the enemy), or else my two sonnes [must] travaile into Holland, and putt themselves into entertaynement under the service and conduct of the Prince of Orange; for they must henceforward maintayne themselves by such entertaynements as they gett in the warres (Earl of Cork to Marcombes 9 March 1641/2, Maddison 1969, 47).

In the event Francis decided to return to Ireland, arriving in time to fight in the Battle of Liscarrol (September 3, 1642), at which another Boyle brother, Lewis, was killed. Meanwhile Robert decided that his health and lack of money ruled out a return to Ireland, and his age made soldiering in Holland an untempting and indeed implausible prospect.[8] He therefore decided to accept Marcombes' offer of hospitality in Geneva, and did not make his way to England until the summer of 1644.

Before leaving Geneva Boyle had a conversation with François Perreaud (1572-1657), who later wrote *Démonographie, ou traité des démons*, which Boyle then arranged to have translated into English by Peter du Moulin (the younger, 1601-1684). In a letter prefixed to the English edition Boyle recalled that "the conversation I had with that pious author during my stay at Geneva, and the present he was pleased to make me of this treatise before it was printed, in a place where I had opportunities to enquire both after the writer, and some passages of the book, did at length overcome in me (as to this narrative) all my settled indisposedness to believe strange things." Acceptance of at least the *possibility* of diabolic or angelic intervention was common among the intelligentsia in the second half of the seventeenth century. Cudworth pointed out one expedient reason for the belief:

> all these *Extraordinary Phænomena*, of Apparitions, Witchcraft, Possessions, Miracles, and *Prophecies*, do Evince that *Spirits, Angels or Demons*, though *Invisible* to us, are no *Phancies*, but *Real and Substantial* Inhabitants of the World; which favours not the *Atheistick Hypothesis;* but some of them, as the Higher kind of Miracles, and Predictions, do also immediatly enforce the acknowledgment of a *Deity*: a Being superiour to *Nature*, which therefore can check and controul it; and which comprehending the whole, foreknows the most *Remotely distant*, and *Contingent Events* (Cudworth 1678, 715).[9].

In a manuscript draft ("Loose papers whence some things are to be extracted for the Discourse of the causes of Atheism") Boyle considered three objections that might be made against such a belief: the implausibility of the standard means of bringing about such intervention; the unreliability of the witnesses; and the impossibility of incorporeal beings interacting with matter. He agrees that the first objection, "urg'd with great confidence, and not without much show of Reason" is a strong one, but suggests that "we men understand very little of the nature, customes, & government of the Intelligent creatures of the spirituall world: and particularly what concernes the Falne Angells or bad Daemons. And therefore they being themselves invisible to us, and capable of working in wayes that our sences cannot discerne; and being Agents of great craft & long experience; tis no wonder that many of their actions, thô never so pollytickly contrived & carried on, should seem irrationall to us: who know so little of their particular inclinations & designes, and the subtil & secret methods in which they carry them on."

The second objections he also accepts, though not wholly: "thô upon particular & cogent proofe I beleeve some of them to be true … yet I reject or distrust far the greatest part, as not being soe attested." The third he rejects as being simply inconsistent, for the human soul is accepted as incorporeal, and it works (though we know not how) on matter (BP 2:105).

When Boyle arrived back in England in mid-1644 at the age of 17 he was quickly reunited with his sister Katherine who seems immediately to have re-adopted the semi-maternal role she had no doubt often played after the death of their mother. She was concerned in a variety of other ways to look after his welfare, both spiritual and worldly. She was, for example, the immediate cause of his getting to know the members of the Hartlib circle.[10]

At this time Boyle settled in Stalbridge (on an estate left to him by his father) and occupied himself mainly in writing or planning works in ethics and theology. Much of his time during the early part of this Stalbridge period was spent in moral philosophy -- "My Ethics go very slowly on," he wrote to his sister Katherine on March 30, 1646 (Birch 1772, I:xxx) -- and there was at this stage no reason to think that he would become one of the great natural philosophers of his time. (See further, Hunter 1995b.) He already approximated to the "lay-bishop" that Aubrey was later to find him to be. He was, in fact, a serious, somewhat priggish young man, though he often gave signs of light-heartedness both as a boy and in later life. After his death Gilbert Burnet claimed that "As for Joy, he had indeed nothing of Frolick and Levity in him," a judgement accepted by Steven Shapin, but this fails to allow for the lighter moments that Boyle undoubtedly enjoyed.[11]

At Stalbridge, about 1649, Boyle began to be interested in experimenting, but was hindered by the fact that he could not obtain a furnace. Stalbridge was far enough away from tradespeople who could make such an item and the furnaces Boyle ordered tended to arrive "crumbled into as many pieces, as we into sects," leaving Boyle to attempt "such experiments, as the unfurnishedness of the place, and the present distractedness of my mind, will permit me" (Birch 1772, I:xxxxvi; xli).

Boyle was troubled throughout his life by the fragmentation of Christianity. Among "the giddy multitude … this multiplicity of religions will end in none at all," he wrote to John Mallet in 1652,[12] and at the

very end of his life he expressed in his Will the wish that the Boyle lecturers should, when "proveing the Christian Religion against notorious Infidels (*viz*), Theists, Pagans, Jews and Mahometans, not [descend] lower to any Controversies that are among Christians themselves."[13]

Eventually, however, a furnace did arrive, and Boyle found himself "so transported and bewitched [as to] fancy my laboratory a kind of Elysium … . I there forget my standish and my books, and almost all things" (Boyle to Katherine Ranelagh, Aug 31, 1649, Birch 1772, I:xlv).

Boyle was never a student at a university. Nor was he ever a fellow of an Oxford College, though that too has been claimed on his behalf (Dutton 1951, 20), but it was to Oxford that he removed after his time at Stalbridge, and it was there that his interest in natural philosophy first flowered. Before taking up residence in Oxford however he paid two lengthy visits to Ireland during the early 50s (for a year from June 1652, and then for eight months from Oct 1653), and it was from that "illiterate country" that he wrote to Clodius, probably toward the end of his second Irish visit, in the spring of 1654:

> For my part, that I may not live wholly useless, or altogether a stranger in the study of nature, since I want glasses and furnaces to make a chemical analysis of inanimate bodies, I am exercising myself in making anatomical dissections of living animals: wherein (being assisted by your father-in-law's friend Dr *Petty*, our general's physician) I have satisfied myself of the circulation of the blood, and the (freshly discovered and hardly discoverable) receptaculum chyli, made by the confluence of the venae lactae;[14] and have seen (especially in the dissections of fishes) more of the variety and contrivances of nature, and the majesty and wisdom of her author, than all the books I ever read in my life could give me convincing notions of (Birch 1772, VI:55).

It was also during this period, no doubt in large part due to Cromwell's extremely harsh treatment of the Irish, that Boyle's Irish properties were made secure and began returning rents to him, ultimately reaching almost £3000 p.a., Hooke told Aubrey. The fact that Boyle's friend Petty conducted the survey on which the disposal of the lands was based can hardly have been to Boyle's disadvantage.

On October 12, 1655, Katherine was in Oxford investigating the suitability of possible lodgings for Boyle. He was to lodge with the apothecary John Crosse, whom Birch felt worthy of mention because he had "a great acquaintance with Dr. *John Fell*,"[15] and the question was, which was the best room for his purposes, and how was it to be furnished?

> My Brother,
> It has pleased God to bring us safe to *Oxford*, and I am lodged at Mr. *Crosse*'s, with design to be able to give you from experience an account which is the warmest room; and indeed I am satisfied with neither of them as to that point, because the doors are placed so just by the chimnies, that if you have the benefit of the fire, you must venture having the inconvenience of the wind, which yet may be helped in either by a folding skreen; and then I think that which looks into the garden will be the more comfortable… (Birch 1772,

VI:523).

The house in question stood on the site where the Shelley Memorial now stands, and his two rooms there seem to have served Boyle admirably, though he later set up a retreat at Stanton St John's, where he could retire when the press of society grew too great in Oxford.

In Oxford Boyle's tremendous output of works in philosophy, theology, and experimental philosophy began. It was here that he published *New Experiments Physico-Mechanical, Touching the Spring of Air and its Effects, Certain Physiological Essays, The Sceptical Chymist, Some Considerations touching the Usefulness of Experimental Natural Philosophy*, and a number of others including *The Origine of Forms and Qualities.*

Boyle's years in London (from 1668 to his death) saw the continuation of his experimental work, along with a number of works on philosophy and theology, including *The Excellency of Theology, Compar'd with Natural Philosophy*, *Considerations About the Excellency and Grounds of the Mechanical Hypothesis*, the *Free Enquiry into the Vulgarly Receiv'd Notion of Nature*, the *Discourse of things above Reason*, *Disquisition about the Final Causes of Natural Things*, and *The Christian Virtuoso*.

In 1691 Katherine died, and Boyle, whose health throughout his life had been poor, died the following week.

2. Religious Views

The seventeenth century is notable not only for the number but also for the variety of arguments which were offered to prove God's existence. Although writers such as Pascal and Bayle felt such arguments to be both unnecessary and unavailable, demonstrations of God's existence were felt by many to be not only possible but desirable, since they were necessary in the fight against atheism.[16]

Descartes, as is well known, felt that God's existence could be, and epistemologically had to be, demonstrated, and offered a variety of proofs to provide such a demonstration. His version of the ontological argument, his proof from the supposed innate idea of God, his proof from the need for an eternal conscious being,[17] and his proof from the need for continuing creation, all found supporters in the later seventeenth century, though the first two were generally held to be unlikely to convince anyone.

Apart from a brief reference to it in the printed works Boyle does not mention the ontological argument (BW 9:413; Boyle 1772, 4:461-2). This distancing was not uncommon at the time. Ralph Cudworth, though clearly fascinated by the ontological argument, recognized that most would "Distrust, the *Firmness* and *Solidity* of such *thin* and *Subtle Cobwebs*," and offered an alternative argument in the hope that it would prove more "Convictive of the *Existence* of a God to the Generality" (Cudworth 1678, 725).

The language of the ontological argument was acceptable, even when the argument's validity was

rejected. Gassendi, for example, agreed that God is that than which nothing greater can be conceived, but denied the validity of the argument which offers this as its main premise (See further Osler 1994, ch. 2).

Nor was the argument from innate ideas more popular. After his dialogue character Cuphophron has espoused it, Henry More has his down to earth Hylobares burst out:

> Well, *Cuphophron*, you may hug your self in your high *Metaphysicall Acropolis* as much as you will, and deem those Arguments fetched from the frame of Nature mean and popular: but for my part, I look upon them as the most sound and solid Philosophicall Arguments that are for the proving the Existence of a God (More 1668, 53).[18]

Boyle, too, held that design arguments were both available and the most likely to persuade rational, open-minded hearers. Such arguments were intended to form a large part of a book on atheism, something he worked on throughout his adult life but never published, though parts of it were used in various other works of a theological nature. Boyle did, however, leave a plan of the intended work, and in the manuscript remains -- seven volumes of correspondence, forty-six volumes of miscellaneous papers and eighteen volumes of notebooks -- there are still a number of unpublished fragments and some longer selections which he intended for this work.

Boyle intended "the little Tract about Atheism" to have three sections:

> In the First of these, the Author represents some Reasons why it should not be thought strange if it be found somewhat difficult to demonstrate the Existence of a Deity.
>
> > 1 The First of these Reasons is, that by reason of the selfe existence and Primity of God, his Essence cannot be Causable.
> >
> > 2 The Vitious Affections & Habits and the depravd frame of mind to be met with in most Atheists do very much indispose them to be convinc'd by the proofes of a Deity that might other wise be sufficient.
> >
> > 3 Since God is a Being whose Nature is the most singular of all, there must necessarily belong to him divers things, not to be paralleld.
> >
> > 4 The Difficulty of such speculations as belong to the Contemplations of Gods Attributes keeps the generality of Atheists & Libertines from being qualifyed for such Enquiries.
>
> In the second section <the Author> haveing premisd, that the foregoing Reasons make it Equitable not to expect metaphysical or rigid Demonstrations of a Deity, but to be content with a moral one, if no better can be had, proceeds to the mediums whereof such a Demonstration can be made up. Such as are

The innate Idea of a Deity

The general Consent of mankind. (To one of which or both may be referrd the Epicurean Anticipation.)

The Reproaches or Boadings & Disquieting Terrors of a Guilty Conscience

The Fabrick & Conservation of the world, especially of Animals

The Nature & Propertys of the Soul of Man

The Lawes of its Union with the Body[19]

The Universal Providence that directs the Affairs of Mankind.

Supernatural Effects whether of good or Evil Spirits (as their Apparitions Action Oracles Predictions &c)

The Patefactions that God has made of himselfe by true miracles. (To which Prophecies are reduc'd.)

The Third section is spent in shewing some of the Reasons why the Arguments proposd in the Second are often unprevalent.

1 And among the Intellectual Impediments the First is, That Atheists often injuriously attribute to the notion of a Deity the fond Opinions or rash Assertions of unskillfull men.

2 Atheists on the other side do sometimes no less injuriously father their owne Errors & mistakes on the notion of a Deity.

3 They do not equitably consider the Nature of the Thing to be proved, & the necessity that thence arises, that the Theory of the Divine Attributes should be lyable to specious Objections.

4 They do not duely consider, that their owne Hypothesis is lyable to some of the same difficulties & Objections, and to others that they cannot solve.

5 The Objections are more popular & easy that are to be made against the notion of a Deity than the Answers to those Objections & the Arguments

> which prove that Notion.

Well, that was the plan, and Boyle certainly thought that the design arguments he intended for section two should convince the open-minded. Moreover, he thought, such arguments should particularly convince those who were knowledgeable about nature, who knew enough about the *details* of the world to be impressed by the intricacy of the presumed workmanship. "[T]here are," he wrote, "positive Reasons afforded by Philosophy to prove a Deity, namely … the Cartesian Idæa, the Originall of Motion, the use of Parts in Animalls, especially the Eye, the valves of the heart, the musculi perforantes & perforati,[20] & the temporary [parts][21] of a foetus <& the Mother>."

The argument from design, said Kant, "always deserves to be mentioned with respect. It is the oldest, the clearest, and the most accordant with the common reason of mankind" (Kant 1781, A623/B651). But, he pointed out, there was a problem with it, a problem which in fact had already been pointed not only by David Hume,[22] but by Boyle's younger contemporary, Charles Blount, who wrote,

> could we conclude any thing from *Miracles*, yet we could never thence conclude of the *Existence* of God. For since a Miracle is Work *limited*, and never implies any but a certain and limited Power: most certain and evident it is, that from such an Effect we cannot rightly infer the Existence of a Cause whose Power is *infinite*, but at most of a Cause whose Power is greater: I say, *at most*; because from many Causes concurring there may follow some Work, whose Force and Power is indeed less than the Power of all its Causes put together, but far greater than the Power of any one of them taken singularly (Blount 1683, 11).

To a large extent Boyle accepted these points. He notes explicitly that none of the proofs he was prepared to offer amounted to a *demonstration* of God's existence, and indeed he felt that a *demonstration* was not possible. A *demonstration* was typically held to proceed from necessarily true premises (often Aristotelian *principles* [23]) via a valid argument to a necessarily true conclusion, and part of what was at issue was whether we should be looking for a demonstration of God's existence, or something less which would nonetheless still be useful in the fight against atheism . "To haue the Science of a thing," said Pierre du Moulin the elder, "two certainties are required. The one is, that the thing be certaine of it selfe and vnchangeable. The second is, that the perswasion which wee haue of it be firme and cleare" (Du Moulin 1624, 162). Gassendi agreed, as did Arnauld and Nicole in the Port Royal Logic (Gassendi 1658, Canon XVI, 144; Arnauld 1662, part IV, ch 8, 323-4, pagination as in the 5th, 1683 edition).

The persuasive alternative to a demonstration was sometimes styled a *proof*, but often people spoke of *moral* demonstrations as opposed to strict, or mathematical, demonstrations. Boyle wrote:

> besides the Demonstrations wont to be treated of in vulgar Logick, there are among Philosophers three distinct, whether *kinds* or *degrees*, of Demonstration. For there is a *Metaphysical* Demonstration, as we may call that, where the Conclusion is manifestly built on those general Metaphysical Axioms, that can never be other than true; such as *Nihil*

> *potest simul esse & non esse* … *&c.* (Nothing can both be and not be at the same time) There are also *Physical* Demonstrations, where the Conclusion is evidently deduc'd from Physical Principles; such as … *Ex nihilo nihil fit* … *&c.* (From nothing, nothing comes) which are not so absolutely certain as the former, because, if there be a God, He may (at least for ought we know) be able to create & annihilate Substances …. And lastly, there are *Moral* Demonstrations … where the Conclusion is built, either upon some one *such* proof cogent in its kind, or some concurrence of Probabilities, that it cannot but be allowed, supposing the truth of the most receiv'd Rules of Prudence and Principles of Practical Philosophy.
>
> And this *third* kind of Probation, though it come behind the two others in certainty, yet it is the surest guide, which the *Actions of Men*, though not their *Contemplations*, have regularly allow'd them to follow (BW, 8:281; Boyle 1772, 4:182-3).

This moral certainty, Locke remarked, "is not only as great as our frame can attain to, but as our Condition needs" (Locke 1690, 4.11.8).

When we look in detail at Boyle's discussions of the various moral demonstrations outlined in his proposed second section it becomes clear that he fancied some considerably more than others. He often mentions the importance of conscience, but concentrates, as far as proofs go, on various design arguments, on arguments based on the incorporeality of the human soul, and on arguments involving miracles. Unlike the clerical authors of the time he pays little or no attention to the arguments from "the innate Idea of the Deity," from "the general Consent of Mankind," or from "the Universal Providence that directs the Affairs of Mankind."

Boyle did not expect his (or anyone's) proofs to convince most atheists:

> you need not thinke it strange, that I never pretended to convert resolved Atheists. For, besides the difficulty of treating clearly and cogently of such abstruse subjects as are many that relate to Atheism; the Will and Affections have so great an influence upon some mens Understandings, that 'tis almost as difficult to make them *beleive*, as to make them *Love*, against their Will. And it must be a very dazzleing Light, that makes an impression upon those that obstinately shut their Eyes against it. 'Tis not by Gods ordinary workes, but by his Extraordinary Power, that such men must be reclaimd to an acknowledgement of his <Existence>. For they that would find the Truth, especially in matters of Religion, must be diligent Inquirers after it, and *may be* strict Examiners of it, but *must not be* resolved Enemies to it. For to such, if to any, God is a Sun, that is not to be discover'd but by <his> owne Light (BP 2:64).

Boyle was aware that most believers held their belief on insufficient grounds (see BP 4:60), but felt himself fortunate in that sound philosophy showed that the religion to which he was born was the correct one. For Boyle, miracles (in particular the miracle of Pentecost) were a crucial factor in opting for

Christianity. The Christian miracles, he felt, clearly bore the stamp of God upon them. There were, he agreed, other miracles or apparent miracles, but the miracles which purported to establish Christianity were neither pretenses nor diabolical, and they *were* miraculous. Locke believed that "Mahomet having none to produce, pretends to no miracles for the vouching of his mission," but Boyle was aware of the argument that the *Koran* itself is miraculous (in view of the disparity between it and what might reasonably be expected of its author in the absence of divine inspiration). He felt, not that this argument was inappropriate, but that it failed the test empirically:

> [T]he *Saracens*, press'd with their Religions being destitute of attesting Miracles, … reply, That though there were no other Miracle to manifest the Excellency of their Religion …, yet the Alcoran it Self were sufficient, as being a Lasting Miracle that transcends all other Miracles. How Charming its Eloquence may be in its Original, I confesse my self too unskilfull in the Arabick Tongue, to be a competent Judge … but the Recent Translations I have seen of it in French, and … Latin, elaborated by great Scholars, and accurate Arabicians, by making it very Conformable to its Eastern Original, have not so rendred it, but that Persons that judge of Rhetorick by the Rules of it current in these Western Parts of the World, would instead of extolling it for the Superlative, not allow it the Positive Degree of Eloquence; [and] would think the Style as destitute of Graces, as the Theology of Truth … .[24]

Boyle does not deny that the style could have been miraculous, and indeed he runs a formally similar argument concerning the Apostles and the miracle of Pentecost: the Apostles' "Hearers … knew it was <not> naturally possible, that uninspir'd Persons, and especially illiterate Fishermen, should <grow> able, in a trice, to make <weighty> discourses to many differing Nations, in their respective Languages" (BP 7:99). Boyle accepts, and indeed uses, the *form* of the Koran argument: it is the premise he disputes.

Boyle is ambivalent about the function of miracles. Generally he regards them as being philosophically relevant after we have a proof of God's existence, something which natural theology will afford us. (Boyle fastens on two main types of design arguments: those involving the complexity of animate beings, particularly very small animate beings,[25] and those which highlight the need to explain the origin and continuing function of natural laws: God must not only sustain God's creatures, Boyle argues, he must also sustain the regularities which we recognize as lawlike.)

Having convinced ourselves of God's existence through the considerations which natural theology makes available to us, and realizing that God is likely to institute a religion to make his nature and requirements known to us, we look to miracles to see which instituted religion is the correct one. However, though in general Boyle argues that accepting something as a miracle *presupposes* God's existence, and so miracles are to be used to *institute* the correct religion rather than to ground its metaphysical basis, he does sometimes urge an argument from miracles which will yield not merely the correctness of Christianity, but the acceptability of religious belief as such. Briefly: we have good historical testimony for the occurrence of miracles, but miracles are possible only if God intervenes in nature (and thereby exists) (BP 5:106-7).

3. Boyle's World View

Boyle had a straightforward notion of creation. First of all God, at a particular, fairly recent, point in absolute time, made matter. Boyle was an admirer of "our *Irish* St. *Austin*"(Birch 1772, I:xxxiii), James Ussher, archbishop of Armagh, who famously propounded what seems to us, though not to his contemporaries, to be a very late date (4004 b.c.) for creation. Boyle saw "no just reason to embrace their opinion, that would so turn the two first chapters of *Genesis*, into an allegory, as to overthrow the literal and historical sense of them" and, noting the implausibility of the claims of "some extravagant ambitious People, such as those fabulous *Chaldeans*, whose fond account reach'd up to 40000 or 50000 years," held that "Theology teaches us, that the World is very far from being so old by 30 or 40 thousand years as they … have presum'd: and does, from the Scripture, give us such an account of the age of the World, that it has set us certain Limits, within which so long a Duration may be bounded, without mistaking in our Reckoning. Whereas Philosophy leaves us to the vastness of Indeterminate Duration, without any certain Limits at all" (BW, 8:21; Birch 1772, IV:11). Revelation gives us (1) truths of which we would otherwise be ignorant, such as "the order and time of the Creation of the World and of the first man and woman"; (2) details of truths which we can otherwise obtain "but very dimly, incogently, and defectively"

> such as … That the World had a beginning, that 'tis upheld and govern'd by Gods general concourse & providence; that God has a peculiar regard to mankind; and a propitious one to good men; that he foresees those future things, we call *contingent*: that mens souls shall not dye with their bodyes, and many other articles of the Philosophers, as well as the Christians Creed (BP 7:242).

Additionally there are (3) "*hints*" which lead us to truths we would otherwise miss, such as "that whatever men have generally believ'd, Vegetables had their Origine independent from the Sun, the earth having producd all kinds of plants a day before God made that Luminary" (BP 7:243). Moreover,

> it ought much to recommend many of the things that Revelation discovers to us, that they are congruous, and if I may so speak Symmetrical to what reason it self teaches us; and this Supernatural Light does not only confirm, but advance and compleat the truths discoverable by the light of nature. For God has so excellently orderd the discoverys he makes of Theological <Veritys> by meer reason, and by the holy Scriptures, that what Revelation superadds to Reason, does both very well agree with it, and supply what was wanting to it, that from them both might result as compleat a body of Theological Verities, as is either necessary or fit for us in our Mortal State (BP 7:245-6). (See further MacIntosh 1992.)

Unsurprisingly, then, Boyle makes a point of attempting to bring his creation story into line with a literal interpretation of the Genesis story. God, he believes, could have started things off earlier or later, but chose not to. Having created matter, he broke it up and started it moving. Sometimes Boyle says he broke it up *by* starting it moving.[26] *Then* he gave it laws, since the "casual justlings of atoms" would not,

Boyle thinks, have given rise to this world.[27] Hooke, explicating Genesis, argued for the same ordering. For Boyle and Hooke, that is, a world without laws is not only possible, our world was such a world for a time. In the previous century Konrad Daspodius held that comets "drift without laws," but by 1686 Leibniz was writing, "God does nothing out of order, and it is impossible even to feign events which are not regular."[28] Leibniz's point was that just as any 'random' sequence of points will determine a curve (actually an infinite set of curves, but Leibniz only needed the lesser claim), so any sequence of events will conform to a regular pattern. Generalizing, we might say that just as points underdetermine equations, so facts underdetermine theories.

It should be noted however that for Leibniz, as for a number of his contemporaries, not all such laws need be laws of *nature*.[29] Malebranche, for example, in his *Dialogues on Metaphysics*, offered no fewer than five distinct types of law: "general laws of the communication of motion, … laws of the union of soul and body, … laws of the union of the soul with God, with the intelligible substance of universal Reason, … general laws which give good and bad Angels power over bodies, … finally, the laws by which Jesus Christ received sovereign power in Heaven and on earth, over minds as well as bodies, not only to distribute temporal goods … but to diffuse (*répandre*) internal grace in our hearts" (Entretiens sur la Métaphysique, in Malebranche 1962, 12:319-320).[30]

Boyle's position is an intermediate one between the claim that some objects or events are lawless, and the claim that lawlessness is impossible. For Boyle, physical objects do exhibit nomological regularities, but this is a contingent fact about the world, or rather, for Boyle was cautious about generalizing, about the spatio-temporal portion of it we occupy. He agrees, however, that there are laws that are *not* laws of nature, with the laws of interconnection between body and soul providing, for him, an obvious example. This interconnection also provides a clear example of a state which God constantly preserves.

After having made matter, started it moving, and given it laws, God then formed the matter into particular structures and shapes, including certain "seeds." Then he added some "seminal" principles. Boyle does not clearly indicate whether or not these are a special subclass of natural laws affecting matter, or whether they are in some way what he sometimes calls "supra-mechanical," though he does point out that if there is a mechanism for animal inheritance, then it would seem to require a framing intelligent agent (BW, 12:445-6, Birch 1772, VI:728-9). His older contemporary Harvey, much admired by Boyle, was in no doubt about the matter, pouring scorn on those who talk

> As if (forsooth) Generation were nothing in the world but a meer separation, or Collection, or Order of things. I do not indeed deny that to the Production of one thing out of another, these forementioned things are requisite, but Generation herself is a thing quite distinct from them all … (Quoted Toulmin and Goodfield 1962, 146).

All this holds for the corporeal universe, as opposed to the three sorts of incorporeal creatures God created or, in our case, continues to create: angels, evil demons, and human souls: the good, the bad, and the imprisoned.[31] The angels were created "before the visible World … was half compleated," but God creates new human souls daily, and moreover works a "physical miracle" to attach them to their

respective bodies (BP 7:243, BP 2:62).[32] Sometimes Boyle felt that although humans are made in God's image they, like other created beings, are "at their best but umbratile, and Arbitrary Pictures of God their Creatour" (BP 4:4). Elsewhere, however, he offers a more traditional account of the soul as the image of God:

> The Christian virtuoso considers the rational soul, not barely as it guides the motions of that living engine, we call the body, but as it is a kind of imprisoned angel, that bears the image of God, and is capable of knowing, both ourselves and him; and by a consciousness of her being his production, is capable of acknowledgeing, loving, and obeying him, and referring to his glory all the excellencies she discovers, both in herself, and in the body she is united to; by which just reference, she is, by his goodness, in his divine Son, made capable of becoming incomparably more knowing, than here she is, and eternally happy with him (BW, 12:504, Birch 1772, VI:775).

Although humans are made in the image of God, they are considerably less clever than the angels,[33] and since it is quite possible that God's primary end in making the universe was to provide a universe for the angels, and not centrally for humans, it is thereby quite possible that the universe will be too complicated for us to understand:

> [I]f God be allowed to be, as indeed he is, the Author of the Universe, how will it appear that He, whose Knowledge infinitely transcends ours, and who may be suppos'd to operate according to the Dictates of his own immense Wisdom, should, in his Creating of things, have respect to the measure and ease of Humane Understandings; and not rather, if of any, of Angelical Intellects? So that whether it be to God or to Chance, that we ascribe the Production of things, that way may often be fittest or likelyest for Nature to work by, which is not easiest for us to understand (BW, 3:257, Birch 1772, II:46).

"[W]e presume too much of our own abilities," Boyle wrote, c. 1680, "if we imagine that the omniscient God can have no other Ends in the framing & managing of Things Corporeal, than such as we Men can discover" (Boyle MS 198, fol. 120). It follows at once that while simplicity may often be our best guide as to what working hypothesis to choose, we should not think it to be inevitably a reliable guide to truth.

Why did God create the universe in this piecemeal way? What is Boyle's rationale for thinking that God didn't just start off by creating matter in motion with the proper directed velocities and letting it give rise to the present world in its own good time? Or why not suppose that he created the *present* world as a going concern? Boyle doesn't tell us, but two points stand out.

First of all, it certainly fits the fact that Boyle has a very limited view of omnipotence.[34] Here he is, for example, bemused by the swiftness of God's creative ability:

> As great a Number & variety of parts as a living Humane Body consists of, 'tis highly probable that the Lump of Stupid[35] matter out of which they were fashion'd, was

> contriv'd into this admirable System; if not in a moment, yet in a very short time. For the sacred story relates, that man was not created till <about> the end of the six dayes work; and since in One day God created all the four footed Beasts, (wilde & tame,) and all the numerous Reptiles that creep upon the Earth after their kind; 'tis no way improbable that among so great a multitude of differing *species* of Animals, or Living Engines, that were made in one Part of the same sixth day, God should make a Humane Animal in an extreamly short time, not to say *in a trice* (BP 4:85). [Here and throughout in quotations, the emphasis is in the original.]

Doing things step by step, fairly quickly, and with moderate success, was quite enough to excite Boyle's admiration for the Almighty and, though he had certainly read Descartes's *Principles* (in which Descartes remarks explicitly that although God *could* have let things work their way from a very different initial state to the present world, *in fact* God started the world off *in medias res*), it is quite possible that the alternative did not strike him as likely: he was not, after all, a mathematician, or even a mathematical physicist.[36]

Given this, and the fact that motion was not natural to matter, but had to be added to it, it would seem plausible to Boyle that God created matter first, and then gave it a push, particularly since the push had to be precisely fine tuned in order to yield just the world we now have. (That matter is not naturally in motion forms the basis of one of Boyle's criticisms of Epicurus. Boyle takes Epicurus to hold that motion *is* an innate property of matter. How then, asks Boyle, are we to explain the fact that it is lost or changed as a result of collision between particles? (BP 2:5).) Additionally, Boyle notices that no system of laws can offer a complete explanation: we also need an account of the initial parameters.[37] But then, since they are logically distinct, why not have them chronologically distinct as well?

Secondly, there are, perhaps, historical reasons. For Boyle is conscious of himself as building on past views, and such views typically treated matter as giving rise to the present world, and, in the case of some past thinkers, at least, as having existed in a constant state for some time before the initiating changes that led to the present world occurred. The notion of a piecemeal creation, that is, fits Boyle's views of God's abilities, fits *Genesis*, and fits the views of previous thinkers. Probably we do not need to look farther for an explanation for his adopting such a view.

(b) *What kind of world is it that God created?*

God created a material world in time and space, but what kind of matter, what kind of space, what kind of time? As to the matter, Boyle agreed with contemporaries such as Huygens and Newton that "Matter [is] in its own Nature but one."[38] However Boyle, cautious as ever, explicitly allows God the possibility of creating matter which is *not* like ordinary matter, and instituting laws which are quite unlike the laws that obtain on earth. His views are worth quoting at length:

> [T]he World must every way have bounds, and consequently be finite; or it must not have bounds, and so be … *infinite*. And if the World be bounded, then those that believe a

> Deity,[39] to whose Nature it belongs to be of infinite Power, must not deny that God was, and still is,[40] able to make other Worlds than this of ours. …
>
> Now if we grant, with some modern Philosophers, that God has made other Worlds besides this of ours, it will be highly probable that he has there display'd His manifold Wisdom, in productions very differing from those wherein we here admire it. And even without supposing any more than one Universe, as all that portion of it that is visible to us, makes but a part of that vastly extended aggregate of bodies: So if we but suppose, that some of the Celestial Globes, whether visible to us, or plac'd beyond the reach of our sight, are peculiar Systemes, the consideration will not be very different. For since the fix'd stars are many of them incomparably more remote than the Planets, 'tis not absurd to suppose that as the Sun, who is the fix'd star nearest to us, has a whole Systeme of Planets that move about him, so some of the other fix'd Stars may be each of them the Centre, as it were, of another Systeme of Celestial Globes … . Now, in case there be other Mundane Systemes (if I may so speak) besides this visible one of ours, I think it may be probably suppos'd that God may have given peculiar and admirable instances of His inexhausted Wisedom in the Contrivance and Government of Systemes, that for aught we know may be fram'd and manag'd in a manner quite differing, from what is observ'd in that part of the Universe that is known to us. … [H]ere on Earth the Loadstone is a Mineral so differing in divers affections, not onely from all other Stones, but from all other bodies, that are not Magnetical, that this Heteroclite[41] Mineral scarce seems to be Originary of this World of ours, but to have come into it, by a remove from some other World or Systeme … .
>
> Now in these other Worlds, *besides* that we may suppose that the Original Fabrick … into which the Omniscient Architect at first contriv'd the parts of their matter, was very differing from the structure of our Systeme; *besides* this, I say, we may conceive that there may be a vast difference betwixt the subsequent *Phænomena*, and productions observable in one of *those* Systemes, from what regularly happens in *ours*, though we should suppose no more, than that two or three Laws of Local Motion may be differing in those unknown Worlds, from the Laws that obtain in ours (BW, 10:172-3, Birch 1772, V:138-139).

Boyle, that is, sees three distinct possibilities: the initial set up may differ, the matter involved may differ, and the laws in question may differ. Moreover the laws, as well as the matter, could have been formed differently by God, and could indeed vary from part to part of the current universe *within* the universe. Clearly the case of varying laws and the case of varying matter may run into each other, but Boyle treats them as distinct possibilities, and gives as an example the possibility of a combination of conservation and non-conservation possibilities: we can envisage bodies with the "power of exciting Motion in another Body, without the Movents loosing its own." Were this to be the case the resulting phenomena would be "strangely diversifyed." Moreover, God may have made a universe, or a part of this universe, which was such that "*some* parts of matter [would] be of themselves *quiescent* … and determin'd to continue at rest till some outward Agent force it into motion [while] *other* parts of the matter [may have] a Power … of restlessly moving themselves, without loosing that power by the motion they excite in quiescent bodies. … Nor is it so extravagant a thing, as at first it may seem, to entertain such suspicions as these. For in the

common Philosophy, besides that the Notion and Theory of Local Motion are but very imperfectly propos'd, there are Laws or Rules of it not *well*, not to *say at all*, establish'd."[42]

Boyle does not use the terminology of absolute space and time, but he remarks that God could have made the world earlier:

> Nor was it his Indigence, that forc't him to make the World, thereby to make new Acquisitions, but his Goodnesse, that prest him to manifest, and to impart his Glory; and the goods, which he so over-flowingly abounds with. Witness his Suspension of the World's Creation, which certainly had had an earlier Date, were the Deity capable of Want, and the Creatures of Supplying it (BW, 1:97, Birch 1772, I:270).

Boyle's general view about both space and time is that since they are

> Primary & Heteroclite … 'tis noe wonder that our Limited & Imperfect understandings should not be able to reach to a full & clear comprehension of them, but should be swallowd up with the <Scruples &> Difficulties that may be suggested by a <bold &> nice Inquiry into things, <to> which there seemes to belong a kind of Infinity (BP 2:53).

He also remarks about the world that

> *if* it be Finite [which Boyle allows as a possibility], then 'tis not in a place (such as the Schools define) after the manner of other Bodys, since there is no ambient Body whose inward surface determines it; and we may conceive it to move several wayes, as upwards or downwards, and yet not to change place, because (as was just now said,) it is in none, and all its Extream parts may keep the same situation in reference to one another (BP 1:64).[43]

Moreover, there is a

> rigid and Philosophical Notion … of rest, which for distinction sake may be called Absolute or Perfect Rest; which imports a continuance of a Body in the same place *precisely*, and includes an absolute Negation of all local Motion, though never so slow or imperceptible; … in this rigid sense of the word Rest, I durst not affirm, that there are any Bodies at Rest in the Universe (at least for any long time) but willingly [allow] it to be made a Problem, whether there be any or no; … perhaps I [incline] to the Negative part of the Question (BW, 6:194, Birch 1772, I:444).[44]

Again, Boyle writes: "Suppose a Ball were in motion, & all the world should be on a sudden annihilated about it; why may not the motion of that Ball be continu'd? there being nothing to stop it; & if it be continu'd, we have a motion where the mobile dos not quitt the neighborhood of som bodys, and approach nearer to others" (BP 1:3).

We have, then, Boyle's view that a body can continue "in the same place *precisely*," that the whole (finite) universe might move in space, and that God could have created the world earlier than he did. Such views do not at least amount to a *rejection* of absolute space and time. Boyle's contemporary, Leibniz, who did reject absolute space, explicitly drew the conclusion that a finite universe could *not* move as a whole in space, and could *not* have been created earlier in time.[45]

The universe God created, then, contains a number of finite *incorporeal* entities, for whom the writ of physics does not run, and a number of material entities, compounded as far as we are aware, of the same matter in every case, set in a space and time independent of them, and subject to a number of God given laws.

4. Laws of Nature

On a number of occasions Boyle assures us that "God [is] the Author of the universe & free Establisher of the Laws of motion, whose generall Concourse is necessary to the conservation & Efficacy of every particular Physicall Agent" (BP 2:132). The trouble is, he seems to have thought that this remark was fairly transparent, and does not trouble to explain it to us. Moreover, he tends to use much the same phraseology on each occasion he discusses the issue. It was a commonplace of the time that Boyle was no stylist -- it was obvious at times to Boyle himself -- but though even the obsequious Budgell remarked that Boyle was "too wordy and prolix," in this case at least he was not wordy enough (Budgell 1732, 124).

It is tempting to suppose that Boyle must have had some reasonably well thought out views on the question of *how* God sustains the world. He was after all one of the most impatient of thinkers when it came to fake or non-explanations, and he was in general very aware of the danger of letting verbal 'explanations' get in the way of real ones. He objected against the scholastics, for example that

> to explicate a *Phænomenon*, being to deduce it from something else in Nature more known to Us, than the thing to be explain'd by It, how can the imploying of Incomprehensible (or at least Uncomprehended) substantial Forms help Us to explain intelligibly This or That particular *Phænomenon*? For to say, that such an Effect proceeds not from this or that Quality of the Agent, but from its substantial Form, is to take an easie way to resolve all difficulties in general, without rightly resolving any one in particular; and would make a rare Philosophy, if it were not far more easie than satisfactory … (BW, 5:351-2, Birch 1772, III:46-7).[46]

On the other hand, in theology he was more likely than elsewhere to let things get by, since he was convinced in advance that his theological picture was the right one, and he was used to stifling doubts about theological claims. Writing about himself in the third person as a young man he speaks of the "fleeting Clouds" of doubts which never ceased "now & then to darken /obscure/ the clearest serenity of

his quiet: which made him often say that Injections of this Nature were such a Disease to his Faith as the Tooth-ach is to the Body; for tho it be not mortall, 'tis very troublesome" (BP 37:182r). (These doubts persisted: see Hunter 1990, 410.)

Moreover, he had a well worked out doctrine concerning the limitations of reason, and often points out that we should not expect fully to understand God's workings, for God is, after all, "<a Being> of a most Primary and most singular Nature" (BP 2:107). (For Boyle on the limits of reason see Wojcik 1997.) Furthermore, he was willing to admit the impossibility of our understanding -- at least given the present limitations on our intellects -- even quite ordinary and lawlike matters, e.g., the way in which the human soul and human body interact. How God could have created the world, and how it is that he can intervene in it, are matters as mysterious to us as how mind and body can interact, and that is a total mystery.

Sometimes, Boyle remarks, our ignorance of things has to do simply with our lack of knowledge of the inner or hidden workings of a thing. He offers his, and indeed the century's, standard example of clocks which may have various internal mechanisms to produce the same outer effects. Thus he remarks that "we know in general, that digestion is made by some *Menstruum* or subtile substance in the Stomach; thô we know not the particular nature of that substance, (as whether it be Acid, Urinous, &c.)". Sometimes, though, our ignorance is of a deeper, richer variety:

> *sometimes* … we are not able to conceive the *Modus* of a thing, soe much as *in general*, or, as to the *possibility* of it, (abstracting from the positive Proofs that such a thing is) as, when we cannot conceive, how the Rational Soul can stop or determine the motions of the <humane> Body. And in this latter case, our not knowing the *Modus* of a thing, is usually more than a bare Ignorance, and inclines us to frame Objections against the Truth or Existence of the thing: because oftentimes the Incomprehensiblenes of the *Modus*, is grounded upon some thing that we conceive to be in the case, repugnant to the Laws or Course of Nature, or to some Dictate of right Reason: as, in the instance newly mention'd, it seems repugnant to the nature of things, that an Immaterial substance, not being Impenetrable, can resist or reflect the motion of a Body &c (BP 1:129).

Boyle was impatient with the Cartesian suggestion that we might be able to alter the direction though not the quantity of motion, not for Leibniz's reason that the notion of quantity of motion required a confusion between momentum and kinetic energy,[47] but for the straightforward reason that interfering with the directed velocity required as mysterious an interaction as altering the 'quantity of motion' would. He was aware of the Cartesian claim "that the rational Soul doth [not] give any motion to the parts of the Body, but only *guide* or *regulate* that which she finds in them already" (BW, 9:379, Birch 1772, IV:416), but that, he felt, did not really solve the problem, for that interaction was as mysterious as an energy introducing one: "I do as little conceive how the motions of the *Conarion* can work upon an Immaterial soul, as how any other part of the Body can do it. Nor do I conceive how an Immaterial Soul can work upon the *Conarion* its self, more then it can upon any other part of the Body" (BP 1:128), and he notes that it will not "suffice to object, that the human will does, in these cases, not produce any new motion, but only determine[s] the motions of the spirits, and by their means of the locomotive organs. For to put a check, at pleasure, to the motion of a body, that does already actually move in one line, and determine its

motion to continue in another, that is perhaps differing from it, or even opposite to it; to do this, I say, without opposing to the moving body, some other body, which, by its resistance and situation may change its former course, is not a mechanical operation" (BW, 12:480, Birch 1772, VI:756). A change of direction, just as much as a change in the 'quantity of motion,' is in fact as mysterious and inexplicable, if done by incorporeal means, as the introduction of energy into the system would be.

5. Boyle's Law

Many of us learned at school that Boyle's Law holds for ideal gases and can be summarized as PV = k, where k is a constant, and P and V are pressure and volume respectively. This law does stem from Boyle's work, but it is not what Boyle took himself to have demonstrated.[48]

Boyle was arguing specifically against a Jesuit scientist, Franciscus Linus, who claimed, not that ordinary atmospheric air does not have any pressure (a spring), but that its pressure was not sufficiently powerful for it to do all the things it does in fact do. So Boyle decided on an experiment to show the way in which, as we would say, the pressure and the volume of the air vary, when the air is, in Boyle's words, either 'compressed or dilated.'

He and his assistant, at the time Robert Hooke, made a J shaped tube and began to make a few measurements, but "were hindered from prosecuting the trial at that time by the casual breaking of the tube."

Subsequently they made another, larger, better piece of apparatus, and taking particular care that the measurements should be accurate, tested the hypothesis "that supposes the pressures and expansions to be in reciprocal proportion." The results are set out, with misprints, in two tables, and Boyle's conclusion was that the experimental findings matched the predicted results very well in the case of compression, less well in the case of rarefaction. Boyle suggested that the divergence from the expected result in the case of rarefaction may have been due to "some little aerial bubbles in the quicksilver" ("so easy is it in such nice experiments to miss of exactness," he added).

Now, what did Boyle take himself to have shown? First, that there is, as a matter of experimental fact, a spring to the air: this is not in the sense in which Boyle understands the term, any longer an hypothesis: it is now obvious from the experimental results: what explains, or purports to explain this fact will be a theory or an hypothesis, but the result itself is in no sense an hypothesis. As Boyle said

> …to determine whether the motion of restitution in bodies proceed from this, that the parts of a body of a peculiar structure are put into motion by the bending of the spring, or from the endeavour of some subtle ambient body, whose passage may be opposed or obstructed, or else its pressure unequally resisted by reason of the new shape or magnitude, which the bending of a spring may give the pores of it seems to me a matter of more difficulty, than at first sight one would easily imagine it. Wherefore I shall decline meddling with a

> subject, which is much more hard to be explicated than necessary to be so by him, whose business it is not … to assign the adequate cause of the spring of the air, but only to manifest, that the air hath a spring, and to relate some of its effects (BW, 1:166, Birch 1772, I:12).

Secondly, Boyle takes himself to have shown that, for atmospheric air, within the limits of his experimental set-up, "the pressures and expansions [are] in reciprocal proportion," or, as we would say, pressure and volume vary inversely. He doesn’t take himself to have shown anything more than this. He does remark that further experiments may show that the relationship holds outside the boundary conditions imposed by the experimental set-up, but the experiments he has just made certainly don’t show that. What Boyle expressly said was,

> till further trial hath more clearly informed me, I shall not venture to determine, whether or no the intimated theory will hold universally and precisely, either in condensation of air, or rarefaction: all that I shall now urge being, that…the trial already made sufficiently proves the main thing, for which I here allege it; since by it, it is evident, that as common air, when reduced to half its wonted extent, obtained near about twice as forcible a spring as it had before, so this thus compress air being further thrust into half this narrow room, obtained thereby a spring about as strong again as that it last had, and consequently four times as strong as that of the common air (BW, 3:60, Birch 1772, I:159).

Thus Boyle’s Law, for Boyle, was not a universal generalization about ideal gases: it was a strictly limited claim about common or atmospheric air. Boyle did add that "there is no cause to doubt, that if we had been here furnished with a greater quantity of quicksilver and a very strong tube, we might, by a further compression of the included air, have made it counter balance the pressure of a far taller and heavier cylinder of mercury."

But he did not claim that the same ratio between pressure and volume would hold in such more extreme cases. Nor did he claim that there are no limits to the possible compression. It is worth stressing that Boyle had this limited view of his result, for Shapin and Schaffer 1985 suggest that

> The work Boyle undertook in reply to Linus was … done … with a specially constructed J-shaped tube in which pressures higher than atmospheric could be attained. Using this apparatus Boyle showed that if he compressed air twice as strongly as usual he could produce twice as strong a spring. He concluded that the process could go on indefinitely, so that there were no limits to the power of the air’s spring (Shapin and Schaffer 1985, 168-9).

But Boyle was quite happy not to draw such conclusions, simply because his experiments didn’t allow that kind of jump. There are other important ways in which he thought that generalizations about nature might fail of universality. He had a very healthy notion of the complexity of the world, and an acute sense of the difficulties to which even apparently simple experiments could give rise, and perhaps in consequence had more sympathy than stricter theologians for the problems which universe construction

might involve, even for the Almighty.

6. Perception and the Soul

Two distinct notions of the soul occupied centre stage in the seventeenth century. One, stemming from Plato and the Pythagoreans, with theological trimmings by Augustine, had been given immense prestige by Descartes' championing of it. This view was what Geach has called the "savage superstition ... that a man consists of two pieces, body and soul, which come apart at death." Geach adds, "the superstition is not mended but rather aggravated by conceptual confusion, if the soul-piece is supposed to be immaterial" (Geach 1969, 38).

The second main account, stemming from Aristotle, had been taken over and made Christian by St Thomas Aquinas.[49] In this account the soul was, though incorporeal, not simply a separate bit attached to the body, but was the form of the individual animal in question, whether human or not. Aquinas presented arguments to show that human souls were subsistent in view of various capacities they had, and proceeded from there to argue for the possibility of the continuing existence of human souls in the absence of the body. He was, however, clear that the human person (even when the person in question was Christ in human form) was not merely a soul with an attached body, but was the body informed by the soul: if your soul alone were to survive death you would not. Bodily resurrection is essential to the survival and immortality of humans.

Cartesians and Thomists alike believed on scriptural grounds that there were actual cases of separated souls, namely, the angels, fallen and unfallen, so the possibility that the human soul might itself be subsistent was simply the possibility that it might sufficiently resemble an already accepted ontological group: despite the problems that substance dualism raises, a number of which presented themselves clearly to Boyle, there was no *general* problem concerning incorporeal entities, and there were, Boyle felt, strong arguments for the incorporeality of the human soul.

For Boyle, as for other leading seventeenth century figures, perception was a matter of information entering the brain as a result of causal interaction between the perceiver and the perceived object. Arriving at the brain the information was processed by a subsystem or set of subsystems devoted to presenting it to the cognitive system, and to storing it thereafter. The initial processing was done by a system, the *common* sense, that combined the inputs from the various sense organs (left eye + right eye; eyes + ears; etc.) and it was then *imagined* -- that is, an image was formed in the brain though, as Kepler and Descartes noted explicitly, the image was not a literal, optical, image. That apart, seventeenth century thinkers accepted in general outline the position which had already been set out in the thirteenth century by Roger Bacon, who was in turn simply collating the views of earlier Islamic writers on the subject, though of course the details, particularly the details of the causal interaction between percipient and perceived, varied from writer to writer (See further Lindberg 1976, MacIntosh 1983, and Sutton 1998).

Imagination was a matter of material images being formed in the brain. But, it was held by Boyle and others, we have knowledge of things which are literally unimaginable -- that is, they cannot be accurately

represented by a corporeal image in the central nervous system. There were a variety of reasons for this belief. First it was held that there were things which were too large, and things which were too small to be imagined, that is, imaged. Hence some non-material faculty was needed to account for this ability. Additionally, there are things which are not image-able because they cannot be represented accurately by *any* physical system. Boyle's stock example in this area, though not his only example, is the incommensurability of the sides and diagonal of a square. Since $\sqrt{2}$ is irrational no discrete (corpuscular) system can accurately represent both. But we do have knowledge of squares. Therefore we must be employing a non-material system. Also, there were things such as Descartes' chiliagon which, while they could be represented physically, could not (as experience shows) be represented accurately by *our* physical imaging system.

Additionally (a familiar Aristotelian point), our ability to abstract -- to consider universals and not merely particular instances -- was held to provide further evidence for the incorporeality of the soul and hence for the possibility at least of human immortality.

Boyle also noted, as did his contemporary Henry More, the Cambridge Platonist, the occurrence of ecstasies. Boyle, like More, took the existence of ecstasies seriously and, accepting the literal meaning of the term, thought that such experiences showed the actuality of non-corporeal, out-of-body, experiences. Boyle indeed offers the case as a refutation of the Aristotelian view that images are required for human thinking. Locke was more cautious on the issue: "whether that, which we call *Extasy*, be not dreaming with the Eyes open, I leave to be examined."[50]

Thus, for Boyle, souls were almost certainly Cartesian souls, though as mentioned earlier he hesitates about whether or not the human soul may not be a substantial form (BW, 5:300, Birch 1772, III:12).

Given that souls are incorporeal adjuncts of the body, it follows that they are not *materially* destructible, and that the laws of interaction between soul and body are not laws of natural philosophy. Why grass *looks* green is a feature of the world which God decided upon and upholds. His reasons for this decision, says Boyle, were no doubt weighty, but they are, as to us, arbitrary (see, e.g., BP 2:62; 2:105; 9:40; 36.46v). Now, if our souls are non-material, that demolishes at least one philosophical barrier to a belief in an after-life such as is promised by Christianity.

Notes to Robert Boyle

Notes

1. See further Brown 1990, who notes Hume's disparagement of the "passion for hypotheses and systems in natural philosophy" as well as d'Alembert's.

2. Boyle Letters 1:131r; reprinted in Birch 1772, I:cxxx. Birch notes, concerning Boyle's interest in alchemy, that he was instrumental in having "a statute made in the fifth year of King Henry IV against the multiplying of gold and silver" repealed. Every "article, or sentence, contained in the said act, and every word, matter, and thing, contained in the said branch or sentence, shall be repealed, annulled, revoked, and for ever made void; any thing in the said act to the contrary in any wise whatsoever notwithstanding." (Birch 1772, I:cxxxii).

3. See *An Historical Account of a Degradation of Gold, made by an Anti-Elixir: A strange Chemical Narrative*, BW 9:5-17; Birch 1772, IV:371-374. For discussion of this piece see Ihde 1964 and Principe 1998. The Hunter and Davis edition of Boyle's works is now the standard edition, deservedly, but Birch's 1772 edition is still widely available, so I am quoting from Hunter and Davis, but giving page references to both editions.

4. There is no definitive full-scale biography of Boyle. Among the most easily accessible sources are:

1. Hunter 1994a. This contains an excellent introduction by Hunter, as well as the best transcription of
2. Boyle's own third person autobiographical "An Account of Philaretus During His Minority" (BP 37:170r-184v, with some misordering), written between Boyle's coming of age in January, 1648, and July of the next year.
3. Birch's 1744 *Life* (Thomas Birch, *The Life of the Honourable Robert Boyle*, in Birch 1772, I: vi-ccxviii) which includes a shortened version of "An Account of Philaretus."
4. Maddison 1969, which includes an annotated transcription of "An Account of Philaretus …," 2-54.

Recent, important, accounts of shorter stretches of Boyle's life include Hunter 1993; Principe 1994 and 1995; and Shapin 1993.

5. Michael Hunter has pointed out the same suggestion coming from Meric Casaubon: ‘it is not improbable that divers secrets of [chemistry] came to the knowledg of man by the Revelation of Spirits’ (Hunter 1990, 398-9), and Debus notes Pagel generalizing the point: ‘by means of unprejudiced

experiment inspired by divine revelation, the adept may attain his end. Thus, knowledge is a divine favour, science and research divine service, the connecting link with divinity. Grace from above meets human aspiration for knowledge from below. Natural research is the search for God.' (Pagel 1935, 98f, quoted Debus 1965, 21).

6. Such doubts were not less common in the seventeenth century than in any other. See, e.g., Thomas 1973, 6.4, "Scepticism," 198-206.

7. Birch, *Life*, Birch 1772, I:xxvi; see BW 2:86, Birch 1772, I:355.

8. Boyle to his father, 25 May, 1642; Maddison 1969, 48-9.

9. Glanville, in *Sadducismus Triumphatus* (Glanville 1689), argued the same point at length. See further, Hunter 1979; Jacob 1974; and Prior 1932.

10. For further details, see Maddison 1969, 61.

11. Gilbert Burnet, *A Sermon at the Funeral of the Honourable Robert Boyle*, in Hunter 1994a, 55; Shapin 1994, 187.

12. Boyle to John Mallet, 2 Mar. 1641/2: B.M. Add. MS. 32093 (Mallet MSS.), fol. 293, quoted in Underdown 1971, 331.

13. Maddison 1969, 274. Hunter points out that the earliest draft of Boyle's Will mentions only "Atheists and Theists." (Hunter 1994a, lxxxiv, n 76. (Boyle's 'theists' are what we would now call Deists.)

14. The "freshly discovered ... receptaculum chyli (receptacle of the chyle, also known as the receptaculum commune and the receptaculum Pecqueti) made by the confluence of the venae lactae" is now more commonly known as the thoracic duct. The beginning of this duct is the cisterna chyli. The first publication of the discovery was made by Jean Pecquet (1624-74) in 1651 in his Experimenta nova anatomica, though he remarked that he made the discovery some years earlier. In the following year Johannes van Horn (1621-70) published the same discovery, having apparently made it independently (Foster 1924, 49). The venae lactae [the "milky" veins] are the vessels that carry the chyle (lymph given a milky look from the absorption of emulsified fats) from the small intestine to the thoracic duct. (Thanks to Andrew Cunningham for this and other information concerning the history of medicine.)

15. Birch 1772, I:liv. Fell was the Dean of Christ Church who was unorthodox enough to be "determined that even the young bloods of the House should work." (Mallet 1924, 2:427, quoted Cranston 1957, 70). Philosophers remember him as the unfortunate intermediary in 1684 when the King determined that Locke, who had behaved "undutifully to the government" should be deprived of his Studentship, but he lives in popular memory as a result of Tom Brown's impromptu rendering of Martial's "Non amo te,

Sabidi" (*Epigrammata* 1.32) as "I do not like thee Doctor Fell" (etc.). For details see Opie and Opie 1951, 169.

16. See further Berman 1988. The various clerical tracts and published sermons are often philosophically unsophisticated but are nonetheless interesting. See, among others, Charnock 1699, Dove 1605, Edwards 1696, and Pelling 1696.

17. This argument, which can be found in Zeno of Citium (*Nihil quod animi quodque rationis est expers, id generare ex se potest animantem conpotemque rationis*–"Nothing lacking consciousness and reason can produce out of itself beings with consciousness and reason," quoted Cicero, *De nat. deor*. ii 22.), is barely sketched by Descartes, but it was developed at length later in the century by Cudworth, Locke, Bentley and Clarke. See further MacIntosh 1997.

18. Cuphophron is "A zealous, but Airie-minded, *Platonist* and Cartesian, or Mechanist"; Philopolis is "The pious and loyall Politician"; Hylobares is "A young, witty, and well-moralized *Materialist*," who has earlier been converted by the design argument: "The weight of Reason and the vehemence of *Philotheus* [A zealous and sincere Lover of God and *Christ*, and of the whole Creation] his Zeal does for the present bear me down into this belief whether I will or no." (More 1668, 28)

19. For Boyle, as for most of his contemporaries, there are laws that are *not* laws of nature, with the laws of interconnection between body and soul providing, for him, an obvious example. This interconnection also provides a clear example of a state which God constantly preserves: "the very conditions of the *Union* of the Soul and Body; which being setled at first by God's *arbitrary institution*, and having nothing in all Nature parallel to them, the manner and Terms of that strange Union is a Riddle to Philosophers, but must needs be clearly known to *Him*, that alone did Institute it, and, (all the while it lasts) does preserve it." (BW, 10:188-9; Boyle 1772, 5:150. See also BW, 12:380, Boyle 1772, 6:681; BP 9:40; BP 36:46v).

20. These are the muscles (*m. flexor digitorum superficialis* and *m flexor digitorum profundus*) which, with their associated tendons move the fingers of the hand. The tendons of *m. flexor digitorum superficialis* are perforated and are penetrated by the lower tendons. Schupbach 1982 (60-64) provides evidence from a number of sixteenth and seventeenth century texts to show the way in which these tendons were considered "a thing notable and marueilous to behold [which] prudent nature [hath] wrought (Banester 1578, following Columbus 1559)." Paley's early nineteenth century *Natural Theology; or evidences of the existence and attributes of the Deity* shows an equal enthusiasm: "There is nothing, I believe, in a silk or cotton mill, in the belts, or straps, or ropes, by which motion is communicated from one part of the machine to another, that is more artificial, or more evidently so, than this *perforation* (quoted Schupbach 1982, 64)." Both Schupbach 1982, 15, and Cunningham 1997, 109, have an impressive 1685 drawing by G. de Lairesse showing the intersection of the tendons. (Thanks to Andrew Cunningham for drawing these works to my attention.)

21. Conjectured–the edge of the page is torn away. Cf. BP 4:67 where Boyle in a column headed

"Against Atheism" lists "The Eyes of Hawkes and Fishes and the Temporary parts belonging to the Foetus."

22. Now, Cleanthes, said Philo, with an air of alacrity and triumph, mark the consequences. *First*, By this method of reasoning, you renounce all claim to infinity in any of the attributes of the Deity. For as the cause ought only to be proportioned to the effect, and the effect, so far as it falls under our cognisance, is not infinite; what pretensions have we, upon your suppositions, to ascribe that attribute to the divine Being? ... Secondly, you have no reason ... for ascribing perfection to the Deity, even in his finite capacity, or for supposing him free from every error, mistake, or incoherence, in his undertakings (Hume, 1779, Part V).

23. Aristotelian principles were held to be necessarily true, though garnered from experience. After noting that "a deductive proposition ... will be demonstrative, if it is true and assumed on the basis of the first principles of its science (*Pr An*, 24a27-30)," Aristotle tells us that "it is the business of experience to give the principles which belong to each subject. I mean for example that astronomical experience supplies the principles of astronomical science ... . Similarly with any other art or science (*Pr An*, 46a17-21)." *How* these necessary truths are to be derived from experience is not completely clear in Aristotle.

24. John Locke, *A Discourse of Miracles*, (1706, written 1702), in Locke 1823, 9.258; BW 2:452-3; Boyle 1772, 2:298.

25. "God, in these little Creatures, oftentimes draws traces of Omniscience, too delicate to be liable to be ascrib'd to any other Cause. ...my wonder dwells not so much on Natures Clocks (is I may so speak) as on her Watches." (BW 3:223, Boyle 1772, 2:22, a slightly different version is at BP 8:139.) Berman points out (Berman 1988, 7, and 44 n 11) that the concentration on insects is not uncommon, but it is worth noting that many seventeenth century writers emphasized the meanness and contemptibility of insects whereas Boyle genuinely admires the workmanship involved. The virtuoso, he often emphasizes, is, by reason of his expertise, in a better position than the uninformed to see the strength of such design considerations.

26. See, e.g., BP 7:192. Boyle sometimes notices the logical possibility that God might have created matter "incoherent" (e.g., at BW 3:248, Birch 1772, II:38-9), but in general he adopts the position outlined.

27. Boyle makes this point in a number of places. See, e.g., BP, 1:16, 1:18, 2:14; BW 6:194, Birch 1772 I:445; BW 3:259, Birch 1772, II:48; BW 5:353-4, Birch 1772, III:48; BW 11:130, Birch 1772, V:428. The point was generally accepted. Dryden wrote, "No Atoms casually together hurl'd / Could e're produce so beautifull a world." (Dryden 1958, 1:13)

28. Konrad Daspodius, *Brevis doctrina de cometis, et cometarus effectibus* (Strasbourg, 1578), CIII(3), quoted in Ruby 1986, 356. Leibniz 1685, §6.

29. Earlier Descartes had remarked that the laws of nature simply were the laws of mechanics (*les regles des Mechaniques … sont les mesmes que celles de la nature, Discourse* V, AT 6:54). Leibniz thought it was a conceptual truth that the universe was lawlike–whatever happened was *the* law that governed things or, in particular, *that* thing. However, as noted earlier, he too agreed that, *in practice*, we should search for *intelligible*, that is, corpuscular, laws.

30. For further discussion see Sleigh 1990, 158 ff. In the seventeenth century these laws were generally felt to be, from a human point of view at least, the result of arbitrary decisions by God. The view was still common in the mid-eighteenth century when the American Samuel Johnson wrote: "We are, at present, *Spirits* or *Minds* connected with gross, *tangible Bodies*, in such a Manner, that as our Bodies, can perceive and act nothing but by our Minds, so, on the other Hand, our Minds perceive and act by Means of our bodily Organs. Such is the present Law of our Nature, which I conceive to be no other than a meer arbitrary Constitution or Establishment of Him that hath made us to be what we are" (Johnson 1752, §3, 3).

31. Human souls are "imprisoned" by contrast with "the angelical Community … of <Rational & Immortal beings> not clog'd with visible Bodys" (BP 1:66v). See further BW 8:33, Birch 1772, IV:19. In the apparently fragmentary "A Dialogue between the Soul and Body" Boyle's contemporary Andrew Marvell agreed: the soul is "hung up, as 'twere, in chains / Of nerves, and arteries, and veins," but Marvell nicely allows the body a similar plaint: "O who shall me deliver whole / From bonds of this tyrannic soul?"

32. In an earlier tradition time and the angels, along with the heavens and the earth, were co-created, so that there was never a time when the angels did not exist. See St Thomas Aquinas, *Summa Theologiae*, 1a 61.3 c.; 1a 66.4 c; *QD de Potentia Dei*, 3.18 ad 20.

33. This is stressed in *Of the High Veneration Man's Intellect owes to God, Peculiarly for His Wisdom and Power*, BW 10:176-7, Birch 1772, V:142.

34. On this issue see MacIntosh 1991, 1992, and 1994.

35. For Boyle, as for his contemporaries, 'stupid' in such context meant simply 'insensible,' or 'non-sensory.'

36. R. Descartes, *Principles of Philosophy*, 3.45, AT 7A:100. For a discussion of the way in which Descartes's counterfactual views came be taken chronologically see Roger 1982.

37. Boyle argues that this is generally true for scientific explanation, not just for explaining the beginning of the universe. Thus, he writes, "every distinct portion of Matter, … [is in] an Innumerable company of other Bodies … all … governed as well by … *The Vniversall fabrick of things*, as by *the Laws of Motion*

(BW 6:275, Birch 1772, III:298). The philosophical implications of this point are discussed by Michael Polanyi in Polanyi 1958, 328-331. Polanyi makes the Boylean point that "*the class of things defined by a common operational principle cannot be even approximately specified in terms of physics and chemistry*" (329, Polanyi's emphasis).

38. BW 5:305, Birch 1772, III:15. Cf. Newton: "The matter of all things is one and all the same, which is transmuted into countless forms by the operations of nature." (Newton 1962, 341) and Huygens: "[It is] accepted by almost all modern philosophers that it is only the figure and motion of the corpuscles of which all things are composed that produces all the admirable effects we see in nature" (Huygens to Paul Pellisson, August 15, 1679, Huygens 1888, 8:198).

39. 'believe a Deity' = 'believe in a Deity'. Boyle's usage was standard at the time.

40. Reading "was, and still is," for Birch's and the first edition's "is, and still was."

41. Something is *heteroclite* if it is unusual or in some way anomalous. Boyle also refers to God as a being that is "heteroclite."

42. BW 10:174, Birch 1772, V:140, reading "not well" for Birch's and the first edition's "well." The *possibility* that the laws of nature could vary over time receives serious scientific consideration today: see Collins 2001.

43. Already in 1277 Stephen Tempier, Bishop of Paris, had condemned the view that God could not move the Cosmos in a straight line (though doing so would not change its Aristotelian 'place'). The Aristotelian claim that such movement would leave a vacuum was not relevant, for God can bring about states of affairs that are "impossible according to nature." (See propositions 66 and 17 of the 219 condemned.)

44. See further, BW 9:409-10, Birch 1772, IV:459. "To be convinced that there is never a body without movement," Leibniz suggested, "one need only consult the distinguished Mr Boyle's book attacking absolute rest (Leibniz 1704, 53)," and recently Catherine Wilson has concurred: "For Boyle, intestine motion is occurring always, in solids as well as liquids (Wilson 1995, 52)," but Boyle himself was characteristically more cautious: "since I consider that we are not yet sure, but that though many of the parts of solid Bodies may not be *always* moveless, yet some others of them may *sometimes* for a while at least, be at perfect Rest; I shall conclude as I began, and without resolutely denying that there can be any such thing *in rerum naturà*, as absolute Rest, I shall content my self to say, That 'tis not either absurd to doubt whether there be or no; nor improbable to think that there is not, since we have not found it in those very Bodies, where with the greatest likelihood it might have been expected." (BW 6:210-11, Birch 1772, I:457.]

45. See, e.g., §§29 and 55 of Leibniz's fifth letter in the Clarke-Leibniz correspondence, Clark 1738,

4:639, 4:651. For suggestions that Boyle did reject absolute space and time see McGuire 1972, 532, and Alexander 1985, 75.

46. Substantial forms are useless for scientific explanations, and they have as well a number of internal difficulties (see, e.g., BW 5:454, Birch 1772, III:117). However, Boyle does not on this account rule out substantial forms altogether: "when ever I shall speake indefinitely of Substantiall forms, I would always be understood to except the Reasonable Soule, that is said to inform the humane Body; which Declaration I here desire may be taken notice of, once for all (BW 5:300, Birch 1772, III:12)."

47. Strictly, Leibniz distinguished between momentum, mv, and mv^2, that is, twice the kinetic energy. See *Discourse on Metaphysics*, §17.

48. In the mid-nineteenth century James Joule demonstrated that, given certain assumptions about the number, size, and random motion of molecules, if we identify the pressure P on the wall of any vessel containing a gas with the force per unit area exerted by the molecules in their collisions with the container, we can then prove

$$PV = \frac{Nm_0\bar{v}^2}{3}$$

where N is the number of molecules in the container, m_0 is the mass of each molecule, $\bar{v}^2$ is the mean-square speed of the molecules and V is the volume of the container. If we further assume that $\bar{v}^2$ remains constant when the temperature of the gas remains constant, then this formula expresses Boyle’s law, for all the quantities on the right-hand side of the equation are constant.

49. Four important discussions of the issues raised by the Thomistic/Aristotelian account of the soul are Edwards 1979 and 1985, Owens 1974, and Kenny 1993.

50. More 1662, 2:121; BW 12:390, Birch 1772, VI.689 (BP 1.125 has "dare not" for "cannot"); Locke, *Essay*, 2.19.1. That "the soul never thinks without an image," is *De Anima*, 431a, 15-17; St Thomas agreed: "In the present state of life in which the soul is united to a passible body, it is impossible for our intellect to understand anything actually, except by turning to phantasms (*Summa Theologiae* 1:84.7 c)."

Divine Providence

Traditional theism holds that God is the creator of heaven and earth, and that all that occurs in the universe takes place under *Divine Providence*-that is, under God's sovereign guidance and control. According to believers, God governs creation as a loving father, working all things for good. Moreover, it is said, God is an absolutely perfect being. He is, first of all, omniscient or all-knowing: he knows of all truths that they are true, and of all falsehoods that they are false, whether they pertain to past, present or future. And God's knowledge does not change. Nothing is learned or forgotten with him; what he knows, he knows from eternity and infallibly. Second, God is omnipotent or all-powerful: anything that is logically possible, he can do. Finally, God is perfectly good: in all circumstances he acts for the best, intending the best possible outcome. Given these suppositions, our initial expectation would be that creation is ordained to perfect good: that as creator God pitches his efforts, which none can resist, toward accomplishing the greatest good imaginable, and hence that the world in which we find ourselves is, as Leibniz put it, the best of all possible worlds. But alas, the evidence is otherwise. The world may contain much good, but it is also a place of suffering, destruction, and death. Life is brief, and afflicted with sorrows of every kind-as often as not with no discernible purpose at all, much less a good one. And it ends for each of us in personal destruction-in death, which trumps all worldly hopes, and conceals impenetrably any experience that may lie beyond. Nor are these mere human hardships. Every living thing dies, all that is beautiful perishes, everything nature builds is destroyed. Indeed, if science is right not an atom, not a photon will escape the cauldron of the universe's final collapse. How can all of this be, if God's nature is as tradition postulates?

1. Logical Consistency and Inductive Evidence

What is described above is the *problem of evil*. In its classical formulation, it is a problem of logical consistency. The opponent of theism alleges that a triad of properties traditionally held to belong to God's nature-omniscience, omnipotence and omnibenevolence-are not jointly consistent with the existence of evil in the world. An omniscient God, we must assume, would have knowledge of the evil in the world. An omnibenevolent God would desire to halt or prevent it, and an omnipotent God should be able to do so. Yet evil is rife. It must be, then, that God lacks at least one of the triad of attributes, and perhaps all of them. Perhaps as creator he is somewhat in the dark as to what evils may occur, and once they appear it is too late to forestall them. On the other hand, it may be that evil is endemic-built into the structure of any world, so that even God is powerless to prevent it. Or, maybe he just doesn't care, and has long since turned his attention to projects more interesting than nurturing our feeble destinies. Whatever the reason, the argument runs, he is not the God of Abraham, of Jesus, and of Mohammed. Their God simply would not permit the suffering and duress under which all creation labors. So while the presence of evil in the world does not serve to prove there is no God at all, it does show there is no God of the kind adumbrated in religious tradition.

The logical problem of evil may be countered with a logical rejoinder. The fact is that the three perfections described above are not by themselves sufficient to exclude the existence of evil in creation. To get that result we have to add a crucial premise to the argument put forth by opponents of theism: that there can be no justification for evil, no good reason why a God with the attributes in question would create a world that contained it. But why suppose this is so? Perhaps there is some good or goods that are possible only in a world that contains or at least permits evil, and without which creation would be vastly inferior to what it is. If that were true, then an all-good and all-loving God would not shrink from creating a world that contained the evil necessary for that good or goods to be achieved.[1] So there is no final inconsistency here, and the theist may wish to conclude on that basis that the problem of evil is resolved. But not yet. For the opponent may concede that the presence of evil in the world does not *entail* that there is no God of the kind religious tradition postulates. Still, he may hold, it gives us good inductive reason for thinking there is no such God.[2] The pervasiveness and profundity of the evil that occurs, the fact that it so often falls upon the innocent and helpless, and the simple fact that we can see no good coming from most of it are more than enough reason, according to this argument, for any rational person to reject the God of tradition. What good could possibly justify the Holocaust, or wholesale destruction of civilian populations in war? Or, lest the numbers submerge the agony, consider just a single case of innocent suffering, posed by William Rowe-a fawn burned horribly in a forest fire somewhere removed from any human awareness, doomed to days of lingering suffering before inevitable death.[3] We are unable to discern any good coming from this single instance of evil, and the same could doubtless be said for millions of others. What more reason could a rational person demand for rejecting the God of our fathers?

This so-called experiential argument from evil may be met with a response similar to the one directed against the logical argument, for the fact is that it too involves assumptions which, when brought to light, seem questionable. It assumes that for each instance of evil that occurs, we humans will be able to detect any good toward which it is directed, and that we will be able to tell whether the good is achieved, whether it was worth the evil sustained in reaching it, and whether it could better have been achieved without the attendant evil. Again, however, why assume any of this is so? An all-powerful, all-knowing and all-loving God could easily have aims exceeding any we have ever imagined. How they are achieved at all, much less the role sin and suffering may play in their achievement, could in principle escape us utterly.[4] If so, then we would be in no position to make the kinds of determinations about the role evil plays in the world, and how dispensable it may be, that the experiential argument presupposes. Still less should we expect to be able to make such determinations in every case, which is what the argument demands. As with the logical problem of evil, then, the theist may greet the experiential problem with a stand-pat position. Neither argument goes through unless we make assumptions we have no reason to make, and which when brought to light seem positively implausible.

Still, evil is troubling, and anyone troubled by it is likely to be left unsatisfied by the stand-pat response. The Western religious tradition is at home with the concept of mystery: it speaks often of aspects of God and his relationship to the world that outreach us, in that our intellects are not finally able to grasp them. But seldom if ever does the tradition treat mystery as totally impenetrable. Just the opposite: the whole point of the theological enterprise is to enable the believer to understand, however imperfectly, the nature of God and the plan of salvation. It is hard to see how this aim can be achieved if a phenomenon as central as evil must be held to escape all comprehension, nor is there any special reason to expect such a thing. Rather, it is in keeping with the hope of the believer that there should be available some glimpse of the good accomplished through the presence of sin and suffering in the world, even if in the actual struggle with them one's best ally is faith. If this is correct, then the theist should not limit his options to the negative. Beyond pointing out the shortcomings of the opponent's arguments, he can and should try to offer a positive *theodicy*-that is, an account of the role evil plays in creation, and a justification for its presence. Such an effort is likely, of course, to end up incomplete. In particular, the theist may be unable in many cases where evil occurs to point to a good to which it is indispensable. But he may be able to offer a general justification for the presence of evil, and to describe some good or goods which but for the occurrence of evil could not be achieved. The question is whether he can do so without compromising divine perfection.

2. The Free Will Defense

Not all theodicies are plausible, and some are so misguided as hardly to be worth pausing over. It will not do, for example, to claim that evil is nothing but a subjective illusion, that if only we could perceive things clearly we would see evil does not exist. As many have pointed out, even if this were true the illusion itself would still be an evil. Moreover, this stance is hardly in accord with the scriptural tradition, in which evil is cause for the utmost concern, both divine and human-even, in Christian theology, to the point that God's own Son must die to set things right. Nor will it do to say that the amount of evil in the world is negligible, that most people are nice most of the time, and that human sufferings are small and

inconsequential compared with the joys of life. This too makes light of the situation. Perhaps the amount of evil in the world can be overemphasized, but it is certainly sufficient to deserve our attention. Not every life contains more joy than sorrow, and evils such as genocide and full scale war are simply horrendous. Furthermore, evil would be a problem philosophically no matter how little of it there were, unless we could see justification for it.[5] A perfect God does not make mistakes, even little ones.

It may be possible, however, to minimize God's involvement in the evil of the universe. That is the aim of what is perhaps the most prominent strategy employed in recent theodicy, which is based the concept of free will, and its importance in the plan of creation. The free will defense begins by distinguishing two kinds of evil. *Moral evil* is evil that occurs through rational action-that is, through wrongful exercises of will on the part of rational beings. *Natural evil*, by contrast, is owing entirely to the operation of natural causes. To see how this distinction works, we need to realize that moral evil can itself be divided into several categories. First come exercises of will that are sinful in themselves, and these are of two kinds. They include wrongful acts of intention formation, as when one maliciously decides to kill another, and the volitional activity through which we execute wrong intentions-e.g., the effort of will aimed at carrying out the intention to murder. The moral wrong of these exercises of will is *intrinsic* to them. They are sinful in themselves, and would be so even if, through some fortuitous circumstance, the attempt to kill went awry, and the intended victim was not harmed at all. Suppose, however, that the action succeeds, as it does in most instances of wrongful willing. If so, further evil will occur-in the present case, the death of the victim. Now if the victim had died entirely as a result of natural causes, his death would have counted as a natural evil. In this case, however, it counts as a kind of moral evil, for while its occurrence requires the cooperation of natural causes, those causes are set in motion by the killer's volitional activity. Harm and suffering that are caused by wrongful willing count as *extrinsic* moral evil, in that they are caused by acts of will that are morally evil in themselves, or intrinsically.

The significance and pervasiveness of extrinsic moral evil is easy to underestimate, because a lot of the suffering and hardship that belongs in this category tends to masquerade as merely part of the human condition, and hence as natural evil. But it is not so. Many of the hardships that befall humankind-disease, ignorance, poverty and the like-owe their existence at least in part to wrongful willing. The poverty of some is owing to the greed of others; suffering and deprivation may occur because of institutionalized racial and ethnic hatred, or because leaders use their positions to advance their own power and prosperity at the expense of their citizenry, or simply because the cost of defense against foreign enemies brings economic hardship to a nation. In other cases the cause is sheer laziness, or the fact that time and talent that might have been devoted to good are instead consumed by selfish ends. Who can estimate how much of suffering and disease, of poverty and ignorance, or of the threat posed by natural disasters would by now have been conquered were not so much of our energy and resources diverted either to the pursuit of wrongful goals, or to guarding ourselves against those who do pursue them, and mending as well as we can the harm they cause? If human wills were not so often misdirected, human life would be transformed, and the struggles against those evils that seem to us no one's fault much further advanced. A great deal, then, of what we are likely to view as natural evil actually falls under the heading of extrinsic moral evil.

That all of sin and so much of suffering counts as moral evil is advantageous to free will theodicy, for

according to the free will defense moral evil is not to be blamed upon God. It is entirely our fault-that is, entirely the fault of rational beings who employ their wills to pursue evil. This is because we have *free will,* which is to be understood here in what is known as the *libertarian* sense. We exercise libertarian freedom in forming or executing an intention only if our deciding or willing is not the product of deterministic causation-that is, provided there is no set of conditions independent of our exercise of will which, together with scientific law, make it certain that we shall decide or will as we do. Independent conditions-our motives and beliefs, for example-may incline us toward one or another intention or action. But they cannot guarantee it, because what we decide and what we strive to achieve is finally up to us. Were it not so, we could not be held accountable for our actions. We would be no more responsible than someone who acted out of a psychological compulsion such as kleptomania, or who was a victim of addiction, hypnosis or the like.

Given the nature of libertarian freedom, then, our actions are up to us, in that they are not brought about by independent events. And because this is so, according to free will theodicy, moral evil is entirely our fault. God is not to be blamed for it, because it owes its existence to our wills, not to his.[6] God is, of course, responsible for having created a world that contains beings with free will. But proponents of the free will defense can point to two reasons that could justify God in populating the universe with such creatures. First, they are an enhancement to creation. Creatures with free will are sources of spontaneity in the world, able to choose for themselves the principles by which their conduct will be guided. As such, they display the kind of liberty we take God himself to have, and so are made in the image of their creator. Second, God endows us with this power because he desires creatures who will accept him freely, who will love and obey him not because they are programmed to do so, but as a matter of spontaneous choice. That we should come to love God in this way is far more satisfactory than that we should be driven to accept him. As in strictly human affairs, forced affection is a pale substitute for love voluntarily bestowed. But, the argument goes, God cannot endow us with free will without running the risk that some of us, at least, will turn against him, and use our freedom to seek evil ends. True, such ends are usually not achieved unless nature, which is God's creation, cooperates. The bullet could not find its mark or the poison be effective unless the relevant natural laws stayed in place. But freedom would be a sham if an evil will could never have its way, and the locus of sin lies not in the consequences of evil willing but in the willing itself. Moreover, even though the harm we cause through our actions requires God's cooperation, it too would not occur but for our choosing and willing as we do. The price of freedom, then, is moral evil. But moral evil is to be laid at our doorstep, not God's, for it is we who choose it. God merely permits our choices and makes them efficacious. In this he is justified, first because of the good of there being free creatures in the universe, and second because some, and perhaps many or even all, of these creatures will come to enjoy God's eternal friendship, by choosing freely to love and serve him.

The free will defense does not, in most formulations, offer a complete solution to the problem of evil. It deals only with moral evil, and although we have seen that this category covers more than might at first be supposed, it does not appear that all of the sorrows and failures of the world can be gathered under it. Even if the free will defense succeeds then, there will remain a residuum of natural evil to be addressed. It may, however, be questioned whether the defense does succeed. One criticism of it raises a question about the relation between creaturely freedom and God's activity as creator. J. L. Mackie has argued that if God is truly all-powerful, he ought to have been able to create creatures who possessed free will, but

who never did wrong.[7] If that were possible, then we would have had a universe free of moral evil, even though it contained creatures with free will. Perhaps the sinful populace that presently inhabits the world would have lost out on such a scenario: maybe God would have had to create an entirely different crowd. Still, moral evil would have been banished, and the condition of the world doubtless vastly improved. But could God have exerted such control over creation? Proponents of the free will defense have tended to think not. In order for God to provide creatures with meaningful freedom, they argue, God must relinquish control over how that freedom is exercised. Were it not so, libertarian freedom would be destroyed: our decisions and actions would not finally be up to us, but would instead be manipulated by God.[8] Even if they were exempt from natural causation, they would still be determined by God's will, and so would be unfree. Indeed, the argument runs, it would be logically impossible for God to create creatures possessed of libertarian freedom, and at the same time have the operations of their will fall under his creative *fiat*. Now it is not usually considered a failure of omnipotence for God to be unable to do what is logically impossible. We need not, therefore, relinquish the claim that God is all-powerful. Rather, the theist concludes, Mackie is simply mistaken in thinking such a God could create free creatures with a guarantee that they would never sin.

It should be pointed out that in giving this response, proponents of the free will defense are making an important assumption about the relationship between God's will as creator and ours as creatures-namely, that God's will operates in the same way natural causes do. That is, his *fiat* as creator counts as an independent condition or event, which causes the occurrence of what he wills in just the way natural causes produce their effects. So if, as creator, God wills that I decide to attend a concert this evening, then my decision to do so is causally determined, just as it would be had I been driven to it by an insatiable desire for Beethoven. Otherwise, we would not have a violation of the criterion for libertarian free will given earlier. Now we shall eventually see that this model of the relation between God's will and the world is at best unlikely, but let us suppose for now that the theist's answer to Mackie's complaint stands. Is the free will defense then successful? Again, it seems not, for the antitheist can still raise two complaints. First, he may argue, even if the free will defense does not violate God's omnipotence, it still violates his sovereignty. If God were fully sovereign over the universe his rule would be complete. All that occurs would be under his direct control, down to the smallest detail. According to the free will defense, however, this is not so. Rather, as we have just seen, proponents of this kind of theodicy insist that some of what goes on in the world is not under God's control, but under that of his creatures. To be sure, God need not have created free beings, and when they engage in sinful willing he can always thwart their ends by manipulating natural causes. But he cannot stop them from sinning (or, for that matter, from willing well), for both of these lie with the will itself. So in creating free creatures God relinquishes part of his sovereignty over the universe.[9]

Second, the antitheist may argue, the free will defense violates divine omniscience. For if I possess libertarian freedom, then whether I decide to go to the concert tonight is neither under God's direct control nor controlled by natural causes. And if that is the case then God has no way of knowing what I will decide. Like anyone, he can make a lucky guess: he may believe devoutly that I will decide to attend the concert, and that may turn out to be correct. But lucky guesses do not count as knowledge. Knowledge requires reasons, and God can have no satisfactory reason for his belief, if by "satisfactory" we understand what omniscience would seem to require-namely, a reason that guarantees correctness.

Rather, like any observer, God must wait to learn what my decision will be in order to be sure of it. But then throughout the time prior to my act, God is not omniscient. There is a truth about the future he does not know. Thus, the antitheist may conclude, the free will defense is in fact a failure. It exonerates God from direct responsibility for sin, but it does so only by surrendering part of God's sovereignty, and by making him fail, as creator, to be omniscient.

3. God's Knowledge of the Future

It is fair to say that philosophers responding to these difficulties have been more concerned to preserve God's omniscience than his sovereignty. Perhaps this is in part because philosophy is itself a matter of pursuing knowledge, so that philosophers are led to value omniscience more highly. Were we generals, say, or politicians, our priorities might be quite the opposite. In any case, most discussions of the seeming conflict between creaturely freedom and divine perfection have concentrated on the task of reconciling as far as possible the assertion that we have free will with the claim that God is all-knowing. One tactic for so doing is to hold that God cannot be faulted for not knowing in advance how we will exercise our freedom, since until we do there is simply nothing to know. According to views of this kind, not all propositions about the future have a truth value. Some do, of course: it is a necessary truth that 2 + 2 = 4, and this proposition has as much bearing on the future as it does on the present and past. Similarly, a proposition concerning the future may have a truth value when its truth is causally determined. Consider, for example, the proposition that the sun will rise tomorrow. Most likely, it is true. True or false, however, this proposition's truth value is fixed by causes already in place, causes that determine either that the sun will rise tomorrow or that it will not. But now consider the claim that I will decide an hour from now to attend a concert this evening. If I have free will, there are no conditions presently in place that determine whether I will so decide. This being the case, according to the present view, the proposition that I will decide in an hour to attend the concert is neither true nor false. It has no truth value at all, nor does any other proposition that describes a future free decision or action. But then, the argument runs, it is not a mark against his omniscience that in creating us, God does not know how we will exercise our freedom. It is logically impossible to know of a proposition that it is true or that it is false if it is neither. And inability to know what logically cannot be known does not harm God's omniscience, any more than inability to do what logically cannot be done harms his omnipotence.

If correct, this view would indeed reconcile divine omniscience and creaturely freedom, leaving only the problem of sovereignty to be addressed. But there are telling arguments against it. Propositions that venture to predict future free decisions and actions do appear to have truth values. One indication of this is that we believe and disbelieve such propositions, and what is it to believe a proposition but to believe it is true, or to disbelieve it but to believe it is false? Nor does it seem possible to worm our way out of this. Let *p* be the proposition that I will decide to attend a concert this evening. It might be protested that for someone to believe I will so decide is only to believe *p* will *become* true at the appointed time-i.e., at the time of my decision. But that does not solve the problem, for to believe this is simply to believe another future-tensed proposition-namely, "*p* will become true"-which is just as dependent on my decision for its truth as is *p*. Similarly, it will not do to claim that to believe *p* is not to believe it is true but only that it is likely or probable. For to hold these beliefs is just to hold, respectively, that is likely that *p* is true, or

probable that it is true. In short, there seems no avoiding the fact that to believe *p* is to be committed to its truth, pure and simple. Moreover, anyone thus committed would, if I later decide to attend the concert, be justified in saying they had been right about what I would decide, that their earlier belief had been correct. And again, what is it for a belief to be right or correct except for it to be true?

It seems unlikely, then, that one can save God's omniscience in creating the world by holding that propositions about future exercises of creaturely freedom have no truth value. But this is hardly the only option. Another alternative is to hold that God's position with respect to time is such that unlike us, he does not have to wait for the future to unfold in order to know its contents. Such was the view of Boethius, who held that God exists entirely outside of time, in a kind of eternal present to which all that occurs in time is equally accessible.[10] Thus, God is able in a single act of awareness to comprehend all of history, the past and future as well as the present, just as though they were now occurring. Many philosophers have followed Boethius in this, holding that God is in no way a temporal being, but is rather the creator of time, with complete and equal access to all of its contents.[11] And it may well appear that on such a view God's omniscience is restored, in that he has immediate cognitive access to everything that will ever occur. Moreover, there is no conflict with libertarian freedom, since the vantage point from which God knows our decisions and actions is completely external to time. This makes all talk about "when" God knows about our actions pointless. He simply knows them, in a unified, timeless and unchanging act of comprehension that comprises all that ever was or will be.

Some philosophers have criticized the idea that God is timeless.[12] But even if the Boethian position is correct on this score, the usefulness of this means of reconciling divine omniscience and human freedom is highly questionable. The difficulty is that in order for God to exercise full providence over the world, he needs to know *as creator* how the decisions and actions of creatures with libertarian freedom will go. It is hard to see how that is possible on the Boethian view, for even if God is outside of time, his activity as creator is still *ontologically* prior to the activities of free creatures on this account, whereas his knowledge of those activities is posterior to them. Thus, it seems impossible that God's creative will could be guided by his knowledge of our actions, even if, from his timeless perspective, such knowledge is finally available to him. If this is correct, then even the Boethian God runs an immense risk in creating the world. He can only hope that we will use our freedom justly and wisely, perhaps making some allowance for the possibility that we will not, but otherwise simply trusting in the outcome. So although God's omniscience may be restored by placing him outside of time, he is in no way empowered by it. It may be questioned, furthermore, whether this view of things really is consistent with the claim that God is timeless. The Boethian picture appears to call for a kind of transition, wherein God first creates free creatures in ignorance of what their actions will be and then learns about those actions by observation. But if that is so then there appears to be change in God, in which case he would have to be a temporal being after all. Now perhaps there is some way around this problem: maybe as creator God somehow operates in isolation from certain parts of his knowledge, while having access to all of it in his role as knower-and yet remains timeless in both capacities. Still, it is not satisfying that God should be limited in this way. His activity as creator ought to be completely unhampered. Moreover, the bifurcation in God's thinking called for by this adjustment only reinforces the difficulty of treating creaturely decisions and actions as falling under divine providence. As creator, on this account, God really does not know what kind of world he is creating: how evil it will be, whence the evil will arise, and how to anticipate it in

detail in the plan of creation. A better solution would be preferable, if one can be had.

4. Middle Knowledge

A possible solution to this problem was posed by the sixteenth-century Spanish Jesuit, Luis de Molina.[13] According to Molina, God is able to know *as creator* how any exercise of creaturely freedom will go. That is, God knows, for any creature he might create, how that creature will behave in whatever circumstances he might be placed. God is able to know this, moreover, even though the creatures in question will, if created, enjoy libertarian freedom. This kind of knowledge, which Molina called *middle knowledge*,[14] is comprised in what we may call *subjunctives of freedom*. Consider, for example, the situation in which I will find myself later today, when I deliberate about whether to attend the concert tonight. It is possible to formulate two subjunctive conditional propositions about that situation. The first states that if ever I were placed in the circumstances (call them C) that will then obtain, I would decide (freely) to attend the concert; the second states that in those circumstances, I would not so decide. Let these be symbolized as $C \Box\!\!\rightarrow p$ and $C \Box\!\!\rightarrow {\sim}p$, respectively. Both $C \Box\!\!\rightarrow p$ and $C \Box\!\!\rightarrow {\sim}p$ count as subjunctives of freedom, and since we are imagining that I will be placed in C later today, it is plausible to think that one or the other of them is true. Let us suppose it is $C \Box\!\!\rightarrow p$. According to defenders of middle knowledge, God knows prior to any creative act on his part that $C \Box\!\!\rightarrow p$ is true; hence he knows this prior to my existence, and prior to any act of mine. We need not take the "prior" here as temporal, if we hold that God exists outside of time. The idea, rather, is that the truth of $C \Box\!\!\rightarrow p$ is *logically prior* to any creative decision on God's part, and to any doing of mine, in that its truth is fixed independently of these matters. Further, God is able to *know* that $C \Box\!\!\rightarrow p$ is true independently of any decision of his, and without appealing to any actual decision on my part as evidence. Finally, God is armed with true subjunctives of freedom for every other set of circumstances in which I might ever have been placed, and the same for every other free individual he has the option of creating, whether he actually chooses to create the creature or not. In effect, then, middle knowledge gives God advance notice of every free decision or action that would ever occur, on the part of any creature he might create.[15]

Assuming it is a legitimate notion, middle knowledge does much to restore God's providence in creating free creatures. Once armed with information about how such a creature would decide and act in the various circumstances in which he might be placed, God has the option of not creating the creature, or of creating him in whatever circumstances are called for by the subjunctives of freedom God wishes to be reflected in the actual world. Now of course the circumstances in which one creature is placed may depend in part on how others choose to exercise their freedom. But the willings of those others can in turn be providentially arranged, since they too fall under middle knowledge. In principle, then, nothing need occur in the actual world that does not have God's prior recognition and consent, at least. There may, of course, be much that does not go as God would prefer. It is important to realize that middle knowledge does not restore complete sovereignty to God. If $C \Box\!\!\rightarrow p$ is true, then there is no way for God to create me in circumstances C and have me do anything but decide to go to the concert. The best he can do is alter my circumstances to fit some true subjunctive of freedom that has another outcome. And the same goes for the subjunctives of freedom that hold of all other creatures God might create. This means there is quite a range of worlds which, though logically possible, are not *feasible* for God, in that they are beyond

his reach as creator.[16] From God's point of view, free creatures will behave as they will behave, and that is that. Still, God can know in advance of creation what worlds are feasible, and can plan accordingly, which is a vast improvement over the Boethian view. The position as regards omniscience is also improved. There is still a kind of transition called for-this time commencing from a point at which God merely contemplates the possibilities of how things *might* go with creation, to a point at which, having decided what creatures and circumstances will populate the world, he knows how things *will* go. Again, however, it might be possible to work out a way in which the transition can be understood non-temporally. And in any case the Molinist position represents an advance over that of Boethius, in that now God's knowledge about how exercises of creaturely freedom will actually go can be derived from his decision about what creatures and circumstances he will create, rather than awaiting the actual decisions and actions of free beings. This diminishes God's passivity; it enables him to know *as creator* how the history of creation will unfold.

But *is* middle knowledge a legitimate notion? Many have thought not. Perhaps the most serious objection against it is that there does not appear to be any way God could come by such knowledge. Knowledge is not merely a matter of conceiving a proposition and correctly believing it to be true. It requires *justification*: one must have good reasons for believing. But what justification could God have for believing the propositions that are supposed to constitute middle knowledge? The truth of subjunctives of freedom cannot be discerned a priori, for they are contingent. It is not a necessary truth that if placed in circumstances *C*, I will decide to attend the concert tonight. Nor can we allow that God might learn the truth of $C \mathbin{\square\!\!\rightarrow} p$ from my actual behavior-that is, by observing that I actually do, in circumstances *C*, decide to attend the concert. For God could not make observations like this without also finding out what creative decisions he is actually going to make, which would destroy the whole purpose of middle knowledge. Instead of being guided in his creative choices by knowing what decisions creatures would make *if* they were created, God would be presented from the beginning with a *fait accompli*-with the reality that he was *going* to create certain creatures, and they were going to behave in certain ways. For God's options as creator to remain truly open, middle knowledge must have some other justification. Furthermore, it seems clear that observation of the actual behavior of creatures could not possibly inform God of the truth of those subjunctives of freedom that delineate the behavior of creatures he will *not* choose to create, for in their case there is no pertinent reality to consult. Yet Molinism wishes to allow for the possibility of such creatures. It is apparent, then, that neither conceptual resources nor resources founded in the concrete world will enable God to know in advance of his decisions as creator which counterfactuals of freedom are true. If there is a third resource, no one has said what it is. Thus, while God may firmly believe certain subjunctives of freedom, there appears to be no justification available to him that would allow such beliefs to constitute middle knowledge.[17]

Note that the above objection is not based on the claim that subjunctives of freedom lack truth values, or that their truth is not properly grounded.[18] That may indeed be a problem for some subjunctives of freedom, but it is not a problem for $C \mathbin{\square\!\!\rightarrow} p$. On the usual understanding, a subjunctive of freedom counts as true provided that, among worlds in which its antecedent is satisfied, there is at least one in which the consequent is satisfied as well, and which is more similar to our world than any in which the consequent is not satisfied. Now no world can be as similar to the actual world as that world is to itself, and we are assuming that *C* and *p* are true in the actual world. Accordingly, $C \mathbin{\square\!\!\rightarrow} p$ must be true as well. The only

way to avoid this outcome is to deny that propositions like *p*-that is, propositions which describe future free decisions in the actual world-have truth values, and we have already seen that this will not do. So $C \,\square\!\!\rightarrow p$ is perfectly well grounded. The problem is only that it is not grounded in the way it needs to be to serve as middle knowledge. It is not grounded *independently* of God's or my free decisions. In light of this, we can only conclude that the Molinist effort to reconcile creaturely freedom with God's omniscience and sovereignty as creator fails. We have yet to see how God can know as creator what decisions and actions his creatures will engage in, while at the same time upholding the idea that those decisions and actions are manifestations of libertarian freedom.

5. A Weaker Alternative

One may be tempted at this point simply to throw in the towel, to give up the endeavor to reconcile libertarian freedom with divine sovereignty and omniscience. If so, we may still insist on libertarian freedom for creatures. But if we are convinced this is incompatible with holding that God is omniscient, and that everything that takes place in the created world falls under his complete governance, then these claims will go by the board. On this type of view, God is a temporal being who, like us, must await the actions of free creatures in order to know with certainty what they will be. And much that occurs, most especially sinful decisions and willings, will not be of his choosing. Not that he is completely in the dark: God can still have probabilistic knowledge of how his creatures will act, and he can contrive to place them in circumstances designed to elicit if possible whatever behavior will achieve the most good. And of course he still has the power to motivate and punish, so creatures may be guided toward right paths. But on this scenario God's aims as creator can only be achieved-assuming they will be achieved at all-by taking risks. Inevitably, creaturely free will makes for a setting of uncertainty, and only within that setting can God attempt to bring creation to a happy outcome. Yet he proceeds, and his doing so is a measure of his love for us.[19]

Such a position may appeal to philosophers who find the God of perfect being theology too remote and mysterious to equate with the God of scripture. But this viewpoint faces serious problems. Some are relatively specific. For example, it is hard to see how, if even God does not know what they will be, the actions of free creatures could be the subject of prophecy. Yet they often are, in scripture.[20] Also, there will no doubt be many cases where multiple free actions impinge on some outcome God desires. When that is so, the probabilities of those actions need to be multiplied to determine God's assurance of the outcome, which as a result could be minuscule.[21] But the biggest difficulty is that this view places God's fate as creator almost completely in the hands of his creatures. No matter how concerned and loving he may be, or how powerfully he attempts to win us over, we are on this view out of God's control. There is always the chance, therefore, that his plans as creator will be utterly dashed, that his overtures to us will be rejected-even to the point, one supposes, of our all being lost-, that we will use our freedom and advancing knowledge to wreak ever greater horror, and that creation will turn out to be a disaster. Willingness to take chances may be laudable in some cases, but surely this level of risk is irresponsible. Moreover, it is completely out of keeping with both scripture and tradition, both of which portray God as above the fray of the world, unperturbed by its mishaps, and governing its course with complete power and assurance. On the present view, divine governance is a hit or miss affair, in which we can only wait

to see whether a somewhat poorly informed God will manage to bootstrap his way to his objectives. Surely, opponents argue, this gives away too much of the traditional notion of providence.

6. The Traditional Solution

If the views considered thus far all fail, there is no choice but to place the decisions and willings of rational creatures under God's creative authority. Only by so doing can we restore to him complete control over the course of events in the world, and only in this way can he know *as creator* what world he is creating, and so be omniscient. If all of our decisions and actions occur by God's creative decree, then all possible worlds are made feasible for him. He can create as he wishes, with full assurance as to the outcome. And he can know how things will go, in particular how we will decide and act, simply by knowing his own intentions as to what our decisions and actions will be. Clearly, there are respects in which this approach is to be preferred. From the perspective of piety, the versions of the free will defense we have seen so far are all troublesome: they seem to place our concern for ourselves above our regard for God, by maximizing our options at the expense of his. One can readily anticipate the response that if complete sovereignty for God and libertarian freedom for his creatures cannot both be had, then the devout (not to say Godfearing) philosopher would be well served to endorse the former, that anything less is not just out of keeping with the mainstream of theological tradition, but actually borders on blasphemy. Yet we have seen that free creatures are of greater value than the unfree, if only because their greater likeness to God makes them a desirable enhancement to creation. The question, then, is whether placing our decisions and actions under God's creative *fiat* leaves in place anything of creaturely freedom, or of the free will defense.

It may seem obvious that neither can survive: that once the operations of creaturely wills are subordinated to God's will, libertarian freedom disappears, and with it any hope of absolving God of moral evil. But at least where freedom is concerned, traditional theology asserts the opposite. Augustine, for example, held that God moves our wills, working in us both to will and to do of his good pleasure, as scripture says (Phil. 2:13). Yet he insists that this does not diminish our freedom, for if it did we would not be told in the same passage to work out our salvation in fear and trembling.[22] Similarly, Thomas Aquinas maintains that all of our doings, even those in which we sin, are on a par with the rest of creation in having God as their first cause. Only the defect of those actions which is their sinfulness derives from us. Sin, he says, is like limping, in which the defective motion arises from the crookedness of the limb, rather than the power of locomotion that impels it.[23] Like Augustine, moreover, Aquinas sees no conflict between God's activity as creator and ours as free creatures. On the contrary: he holds that God's activity as first cause is actually the cause of our freedom, since he moves us in accordance with our voluntary nature.[24] As to how this can be, it has to be said that Aquinas offers little by way of explanation. There is, however, an interesting suggestion in the *Summa Contra Gentiles*, where Thomas maintains that if the will were moved by an external principle as agent, the movement would be violent, and moves to the conclusion that God *alone* is able to move the creaturely will as agent without violence, since he alone is the cause and sustainer of its being, and thus is able to move it from within.[25]

This suggestion cannot be explored fully here,[26] but there are two things to be said in its favor. The first

concerns libertarian free agency itself, which is often portrayed as a power by which we cause, or confer existence upon, our own actions. Such a view would not accord with Aquinas's claim that only God can move the creaturely will in this way, and in fact it is hard to see how this portrayal of agency can be right. If I confer existence on my decision to attend the concert tonight, I must do so either through some act separate from the decision, or as an aspect of the decision itself. If it is through a separate act, the problem of freedom simply shifts its location. We have to be convinced that this act in turn receives its existence from me, and we appear headed for a vicious regress. But neither does it seem possible for me to confer existence on my act of deciding as an aspect of the act itself. For prior to the act's appearance there is nothing to do the conferring, and once it appears, the conferral is no longer needed. So whatever agency and voluntariness consist in, it does not appear to be an ability to confer existence on our own actions. That is important, because it means that unless we can find a way to ground libertarian freedom in the creative activity of God, the decisions and actions in which it is manifested are likely to have no accounting *whatever*-a situation few philosophers are likely to find satisfying, and which hardly puts me in control of my act of deciding.[27]

A second important consideration has to do with the relationship between God's creative will and the things he creates. We are prone to think of this as an event-causal relation, in which God issues a kind of command, and the command in turn produces the mandated effect. Applied to our example, this would mean that God creatively wills that I decide to attend the concert, and his willing then causes me to decide. And of course this sounds exactly like what Aquinas describes as the violent operation of an external principle. On this scenario my deciding is passive, and hence involuntary, because God's creative *fiat* is an event independent of my decision, which by acting upon me robs me of my autonomy. I am reduced to a puppet manipulated by God, rather than a free agent. Clearly, however, this scenario does not reflect the way Aquinas thinks creation works, and on that score there is reason to think Aquinas is right. For consider again the causal relation alleged to obtain between God's willing and mine. Whatever we take this to consist in,[28] it must exist contingently, for causal connections are not necessary beings. But then this supposed causal connection must also be created by God, and if that occurs through another process of command and causation, we would be facing another regress. The only way out is to hold that God *directly creates* the causal nexus-which is to say that in its creation, the nexus itself, not some command, is the *first* manifestation of God's creative activity. But if God's creative will can be directly efficacious in this task, then it can also be so in his creation of us and our actions. There is, then, no need for a nexus to explain the efficacy of God's creative will, nor is there any causal distance whatever between God and either us or our behavior. Rather, we and all that we do have our being *in* God, and the first manifestation of his creative activity regarding our decisions and actions is nothing short of the acts themselves.

If this is correct, then as Augustine and Aquinas both insist, God's creative activity does not violate libertarian freedom, for it does not count as an independent determining condition of creaturely decision and action. On the contrary: assuming God's own will is free, there is no event in heaven or earth that is independent of my deciding to attend the concert tonight, and which causes my decision. God's creative activity does not act upon me or render me passive in any way, for it consists solely in God's freely giving himself over to being the *ground of being* for me and all that I do. Accordingly, I can still display libertarian freedom. My decision is a spontaneous display of creaturely agency, free in the libertarian

sense because it does not occur through event causality, and because in it I am fully and intentionally committed both to deciding and to deciding exactly as I do. There are no further legitimate requirements for libertarian freedom. There is, of course, something that cannot happen on this view: it is not possible for God's activity as creator to be devoted to my deciding to attend the concert, and yet that I should forebear to decide at all, or decide to do something else. But that is not because if I were to try it, I would find myself in a losing battle with God's efficacious will. It is because there is no manifestation of that will regarding my decision short of the decision itself. The impossibility that God's will as creator and mine as creature should diverge suggests trouble because we can view what goes on either from God's perspective or from mine. That suggests two events, and a potential conflict between them. Properly interpreted, however, the traditional view appears to call for only one event, and as far as *it* is concerned, all the impossibility comes to is that I cannot at once both make a decision and not make it. To be incapable of the logically impossible is not a failure of libertarian freedom.

7. Sin

The traditional view is enigmatic, and a lot more would need to be said to make it convincing. But if something like the traditional view can be made to work, creaturely freedom is indeed reconcilable with divine sovereignty and omniscience. Our destinies are entirely subordinate to God's creative will; he exercises full control in all that we do, notwithstanding the fact that our deeds are fully voluntary, and we have every reason to expect that all that takes place in the world will reflect the providence of a perfectly loving father. As for omniscience, here too there is no difficulty. God knows about our decisions and actions simply by knowing his own intentions, for he wills that they occur. Nor is his will exercised from the fastidious distance preferred by Molinists, in which God creates us knowing what we will do, but has no hand in our actually doing it. Rather, God is as much the cause of our sinful actions as of our virtuous ones, or of any other event. Yet, Augustine and Aquinas would insist, he remains perfectly good and absolutely holy, a being deserving of our complete reverence and absolute devotion. How is such a thing possible?

Part of the answer lies in the fact that even if my act of deciding to go to the concert tonight has its existence grounded in God's creatively willing that I so decide, it is still *I* who act, still I who decide. God's willing that I decide as I do does not make my decision God's. Indeed, if it did, if my decision were predicated of God rather than me, his will would fail to achieve its object. But it is not possible for God's will to be frustrated, as long as what he wills is consistent. So regardless of what we may think of the traditional view's contention that divine sovereignty and libertarian freedom are fully compatible, that view does not take the operations of our will, or the actions founded upon them, away from us. They remain our own. Consequently, any sin they involve remains ours also. Thus, if I decide sinfully to go to the concert tonight-if, say, I am neglecting duties I know should take priority-the sin is mine, not God's. If he is to be faulted, it must be for some other reason. It should be noted, moreover, that God's position in this respect is not much different from what it is on the Molinist account. True, that view takes certain things out of God's hands. Whether I would decide to go to the concert in the circumstances in which I will find myself tonight is not, according to Molinism, up to God. But it is up to him whether I shall be created in those circumstances, and indeed whether I shall exist at all. On both views, God knowingly and

willingly creates a world in which rational creatures sin. The difference is that on the traditional view God does have complete control: he can create any possible world, and he is as much involved as creator in those acts in which we sin as he is in any others. And that means the standard free will defense, which works only by diminishing God's authority and circumscribing his providence, is not available.

But another may be. It must be remembered that even though the actions of free creatures do not escape providence, such creatures are still an enhancement to creation, in that their nature reflects more closely what we suppose to be God's own nature. As such, free creatures are more suited to the kind of fellowship with God that believers understand to be their ultimate destiny. It may be, however, that the achievement of that destiny inevitably involves sin. In part, this is because to have free will is to have a nature that is incomplete, in the sense that what we are never fully determines what we shall do. Rather, we have to complete our own nature, by establishing an identity for ourselves-that is, by adopting the patterns of behavior, and the long term objectives that define our lives. And it may be that in so doing we inevitably find ourselves in rebellion against God, simply because as free beings we take ourselves to be establishing our own destiny-and so make that, instead of obedience to God, our first priority. Second, it has to be remembered that true friendship is always voluntary. If God only *exacts* devotion from us, we are reduced to being his subjects. To be friends with him requires a meaningful and responsible decision on our part to accept the offer of friendship he presents to us. But a responsible choice in God's favor requires that we understand the alternative-which is to be at enmity with him. And there is good reason to think such an understanding requires that we sin. Guilt, remorse, a sense of defilement, and the hopeless desolation of being cut off from God cannot be understood in the abstract, because if they are only understood abstractly they are not *ours*. Only through experience can we understand what it means to be in rebellion against God, and we gain that experience by sinning. By turning away from God we realize what it means to be alone, and we learn that however successful they may be, our own projects cannot satisfy us. Only then are we in a position to choose responsibly to accept God's offer of fellowship. Finally, we must remember the simple fact that if we are to experience a transition that ends in our being united to God, that transition can only begin from a place where we are separated from him. It is plausible to think, however, that there is no morally neutral ground here: that unless we are within the circle of God's love, we must be outside it, and that once we choose voluntarily to stand alone, we are already in an attitude of hostility toward God. In short, if we are to come to God as voluntary agents, it may well be that we can only approach him from a position of sinfulness.

If this is correct, there is a great good that God, as a loving creator, is able blamelessly to will for us, but which in its exercise inevitably leads us into blameworthiness. That good is our autonomy-the thing that makes us most like God, and is the sole means by which we are able to reach friendship with him, but which can be responsibly exercised to enter that friendship only if first employed in a conceit of rebellion, wherein we learn our limitations, and come to appreciate the emptiness of a life based on subjective independence. Only thus are we able to reach a position of moral autonomy from which an authentic choice to enter into fellowship with God is possible. Thus, freedom is indeed crucial to moral evil: the implications of libertarian agency are such that its purpose in God's plan could not be achieved without the occurrence of sin. Unlike the standard free will defense, however, this approach does not endanger God's sovereignty or omniscience. As creator, he is fully involved in those acts in which we sin, for they can occur only through his will. But he incurs no blame for them, for they are our acts, not his, and

although they place us in rebellion against him, they do not put God in rebellion against himself. Indeed, no individual can be in rebellion against his own will. So if the essence of sin is rebellion against the will of God, then even though God is the first cause of those acts in which we sin, it is not possible that he himself sin in their occurrence. It is worth noting, too, that the present view makes it possible to explain what, on the standard free will defense, can only be a mystery- namely, that although all of us possess libertarian freedom, and so have the option of serving God, still *all* humans sin. The reason for this is not that God suffers a terrible run of bad luck in a grand lottery of his own institution. Rather, it is because only by passing through sin that the saved are able to achieve their destiny. By creating us in our sinfulness, God assures that each individual will develop an authentic moral identity, and, if the theistic tradition concerning divine justice is correct, prepares each for the eternal recompense appropriate to his character.

Two objections may be raised at this point. First, one may doubt that the kind of moral autonomy described above is truly authentic, given God's role in our actions. As long as God is in the controlling position this view assigns to him, it might be argued, the apparent moral autonomy of free creatures, and the destiny they achieve through it, is a sham-something visited upon them, rather than legitimately chosen. The second difficulty concerns the destiny itself. It is not a part of our religious tradition that all are saved. St. Paul, for example, seems clearly to have believed that some, the elect, are destined from the beginning for salvation, and others not (*Rom.* 9:10-24), and the same appears true of Jesus himself (*Matt.* 26:24, *Luke* 10:20). And it is part of standard theology that, after death, the saved are joined to God in the beatific vision, a state of eternal and indescribable joy. The lost fare far worse. They are condemned to the bitter and devastating frustration of permanent separation from their creator, and on many accounts to a lot of other miseries as well. Now on the present view, God is as much involved in the rebellion of the reprobate as in the conversion of the saved. And one may well wonder what could justify this. Why should a loving God create creatures destined for damnation?

To the first of these objections it may be responded that although all of our destinies are fully in the hands of God, and all of our actions under his authority as first cause, it does not follow that the choices on our part through which our destiny is achieved are anything but fully authentic, or that the moral identity in which we are created by God is imposed upon us. God's will does, of course, determine our decisions in the logical sense: if we know his will for a creature, we can always infer that creature's fate. But that is only a deductive relation among propositions; in itself, it does not necessarily imply any relation among real entities that curtails our freedom. And if, as was suggested above, the first expression of God's will regarding our choices is those very choices themselves, then there is no independent occurrence in the world or in God before which we are rendered passive. On the contrary: our acts of will are fully endowed by God with the characteristics of agency. Thus, our moral identity is in no way forced upon us. It is an identity fully of our own choosing, adopted by us in complete freedom and integrity, notwithstanding the fact that our doing so is entirely within the providence of God. Believers should not, then, fear that their destiny is a sham, or find fault with God for creating them what they are. Rather, the appropriate response would be to follow the scriptural injunction to work out one's salvation in fear and trembling, knowing that an all-powerful and provident God is also working through us to achieve his ends.

As for the second objection, whatever the sufferings of the lost may be, theologians have always agreed that the greatest evil they sustain is final and irremediable separation from God. Nothing could be worse than to be cut off from the love and friendship of a father whose power extends to every detail of the universe, and who invites us to a share in his very life. But if this is the greatest evil of damnation, then no one who ends that way is treated unfairly, for this separation is precisely what one chooses by insisting on a life of rebellion rather than seeking reconciliation with God. Indeed, having once created beings destined to be lost, it is hard to see how a loving God could do anything but honor their choice in the matter.[29] What is troubling, rather, is that he should create such beings at all, much less will their performance of the very actions through which they reject him. It may be argued, however, that even here God's love is at work. He cannot, of course, directly intend the rebellion of sinners, nor the destruction of the finally unrepentant. But the lost are full participants in securing their tragic destiny; and while a life ruined by final rebellion is morally indefensible, it is still morally meaningful. Through their actions, the lost carve out for themselves a character which, though not upright, represents a real option for a free creature. Thus, the argument runs, to the extent that moral autonomy is a good it can be willed for a creature by God even when it takes this form. Furthermore, it is claimed, it is a mistake to think that God is not lovingly involved in the lives of the reprobate, or that he would have been more loving had he not created them. On the contrary: what is meaningless is to suppose that God would have shown greater love toward the lost by omitting them from creation. What is not there cannot be loved. Equally, it is meaningless to think the lost would be better off had they not existed.[30] What does not exist is neither well nor poorly off, nor anywhere in between; and it is as good for the reprobate to have life, the opportunity for salvation, and an autonomous choice as to whether to accept it, as it is for the saved. What is not good for them is the use they make of the opportunity, in choosing to be without God. But that is fully their decision, and its consequences are fully earned.

8. Moral Evil and Defeasibility

If the sort of view outlined above is correct, there is ample reason for God to create a universe in which there is moral evil, for only through the presence of moral evil is it possible for creatures like us to develop a legitimate moral identity, and make an informed and responsible choice to accept or reject God's offer of friendship with us. It is important to see that on such a view, moral evil is not treated as a causal means to the good of our having friendship with God. If that were so, opponents could justly object that God could simply have created us in such friendship from the start, and the defense would fail. Rather, the good on which this kind of theodicy is based is a free and informed choice that can only be made from a position of sinfulness. Rather than constituting a causal *means* to our establishing our own stance toward God, sin is an indispensable *part* of the process-something without which a legitimate choice for or against God's friendship is not just causally but conceptually impossible. But that is not all. In the case of those who choose in God's favor, at least, moral evil is *defeated* in that it is bound up in a total state of affairs that counts as a far greater good, in which the evil is addressed and overcome. The very autonomy that the sinner once insisted upon is surrendered to God, thus becoming the foundation for a new understanding and a richer relationship, in which one is able to act as an informed and wholehearted participant in the divine enterprise of working good. Sin does not function as a causal means in this process, nor is it simply overbalanced by some other good with which it coexists. It

encountered and overcome, through the providential operation of God in creaturely freedom.

The idea that evil is defeasible was developed first by Roderick Chisholm.[31] It is an especially useful notion for theodicy, in that when evil is defeated, the usual objections to the presence of evil in the plan of providence are turned aside. If evil were only a means to good, and were simply outweighed by the goods to which it leads, antitheists could legitimately object that God could have created a better world simply by omitting the evil and creating those goods outright, or obtaining them through means that were not evil. By contrast, when evil is defeated it is caught up in a larger state of affairs that constitutes a far greater good, but not by containing components that might have occurred independent of the evil in question, and simply outweigh it. Rather, the evil is addressed within the larger state of affairs in such a way that it becomes integral to the good through which it is defeated. The defeat of evil is, moreover, an especially impressive sort of good. That Beethoven should have overcome the natural evil of his deafness to write the music he did, for example, strikes us as an amazing good-one far greater than what would have been accomplished had Beethoven written the same music (assuming that to have been possible) with good hearing. Similarly, that moral evil is overcome through the process by which sinners are brought into a right relationship with God may be considered a far greater good than would have been accomplished had he made us a community of spiritual lotus eaters, whose relationship to him, if any, was founded on no meaningful decision, but simply upon our never having had the experience that would make anything else possible. Indeed, given the moral vacuity of such an existence, it is not obvious that such creatures would even be fit for divine friendship, much less able to make the decision through which that relationship is brought to pass.

But of course the same does not occur in the case of the lost. Their rebellion is permanent, and is not overcome through any action of theirs. The antitheist may wish to argue that in this case it is evil that triumphs over good. The character of the lost is permanently corrupted: any virtue that was theirs is turned to wrongdoing, and any hope that they might even achieve peace with God, much less be of useful service to him, comes to nothing. Thus, it might be claimed, the very existence of the reprobate stands as a gratuitous and unanswered defilement of creation, in which evil is victorious. Can the theist point to anything that might reverse this verdict? One possibility is that God himself could take action specifically aimed at defeating all moral evil. This, of course is the defining theme of Christian soteriology. In that tradition, all sin is defeated through the paramount manifestation of God's love for the world, the redemptive suffering of Christ, which could not have occurred unless there were sin, and which makes possible God's offer of salvation to humankind. Not all sinners may accept the offer, but God is reconciled to all, in the sense that the substitutionary atonement of Christ covers all wrongfulness. For the Christian believer this is a *sine qua non*: nothing but the sacrifice of a being who participates fully in the divine nature is sufficient to satisfy fully the demand of divine justice, and unless that demand is satisfied friendship between God and humankind is impossible. Thus the redemptive suffering of Christ is for Christians the ultimate act of mercy and compassion on God's part toward all sinners, and the ultimate defeat of moral evil.

This kind of answer is, however, confined to a particular religious tradition. Is a more general solution possible? There are at least two lines of response the theist can take up at this point. First, he can argue that the moral evil wrought by unrepentant sinners is defeated through divine justice. Evildoers who

refuse reconciliation with God receive a recompense addressed precisely to their offense: a permanent state of separation from the God they reject. The destruction this entails befits their situation, but it is also a destruction the wrongdoer chooses, and his choice is honored by God in the outcome. Thus, religious apologists argue, the fate of the reprobate is a manifestation not only of God's love for them, but also of his justice. Without sin, it is held, much of God's goodness could be displayed in the world, but his justice could not. Not that God does not forgive the unrepentant; he does, but his forgiveness is rejected, and that is what seals the sinner's fate. So while the sinfulness of the unrepentant is not overcome through their accepting salvation, it is defeated through God's justice in honoring their rebellion. Secondly, there is the fact that the sinner's deeds are visited upon others in the world, who must cope not only with the suffering and hardship that results, but also with the very fact of sin: with knowing they have been denied the dignity appropriate to rational beings, and instead made the object of malice. Here too, the theist might argue, it is possible for sin to be defeated, by being pointed out and corrected, and above all by being forgiven. In admonishing and forgiving those who sin toward us, we ally ourselves with God in the struggle against moral evil, by refusing to lapse into vengefulness and self-pity, and instead focusing ourselves, and if possible the sinner as well, on the higher things of God. This also is a good to which sin is integral, rather than constituting a mere causal means, and which makes the world far better than it would be if sin never occurred.

9. Suffering

The position outlined above depends heavily on the idea that in the plan of providence moral evil is defeated, rather than simply being outweighed by some good to which it is a means. The evil of sinful willing is overcome when autonomy that is wrongfully willed is surrendered to God in repentance and conversion, or when the sinner is left to the just deserts of willing to be separated from God. It may fairly be argued, however, that the defeat here pertains primarily to intrinsic moral evil-that is, to sinful willing itself-rather than to the harm caused by it. Both conversion and reprobation may refute the sinful will, but they do not seem to alleviate or otherwise overcome the suffering caused by it. The idea of forgiveness may address the latter to some extent, but it is not entirely clear how. And even so, it may be claimed, much suffering is not, or at least not obviously, the result of wrongdoing. The pains and anxieties of daily living would doubtless be lessened if wrongful willing did not occur, but there would still be danger and disease, accidents, natural disasters, occasional deprivation, the sufferings of old age, and eventual death. Theodicy has to deal with these evils too, and as in the case of sin, it will not do to claim simply that they lead to some greater good that outweighs them. For as in the case of sin, the antitheist could then argue that God could as easily have created the world so that the resultant good would be achieved by means that did not involve suffering, or would simply appear without any means at all. How, then, might the theist respond here? Can the concept of defeasibility be developed so as to cover suffering as well as sin?

One indication that it can is the disdain we would have for a world in which there were no suffering or hardship to be faced, but instead only endless gratification. As usually formulated, the argument from evil is based on what appears to be a false presumption. It imagines that the ideal world for a loving and compassionate God to create must be what John Hick describes as a hedonistic paradise: a place devoted to human enjoyment, in which comfort and convenience are maximized, and pain and deprivation evil

have little or no place.[32] If not banished completely, they must be held to the minimum necessary to guarantee to God's creatures the most pleasant existence possible. Now obviously, that is not the sort of world we have. The amount of suffering is immense-far more, certainly, than it would be if God's aim were to maximize worldly joy. But the appropriate conclusion, the theist may argue, is not that the universe is not the creation of a provident God. For consider how we react to people whose lives have little to distinguish them except that they appear-perhaps deceptively-to be filled with enjoyment. There is a tendency, when we suffer one or another of life's ills, to envy such people: to wish our own existence could be as theirs seems to be, rather than the painful drudgery of the moment. But the truth is that we seldom admire those who appear to have a life of ease, nor are we likely to consider that kind of life very well spent. What we admire are lives of courage and sacrifice: persons who overcome hardship, deprivation, or weakness to achieve some notable success; who stand, perhaps not even successfully, against some great evil; or who relinquish their own happiness to alleviate the suffering of others. How would such lives be possible if natural evil did not exist?

Still less would we respect an entire world devoted to nothing but enjoyment. Imagine a society in which everyone has an electrode implanted in their brain, which, when a current is passed through it, causes intense euphoria, unmatched by any other pleasure. One simply needs to be attached to a power source, and the simple push of a button yields ecstasy. And that is all anyone cares about. Agriculture, commerce, government, and social institutions are organized toward but one goal: to maximize the time each person can spend plugged in, lost in self-stimulation. Individual lives are conducted with the same aim. Work is still necessary, but it is held to a minimum, and contact with fellow human beings has no purpose other than to keep things running smoothly, so that the pleasure of all can be maximized. Now if the antitheist ideal of creation were correct, this type of society ought to represent a high order of human existence-better by far than the world in which we presently find ourselves. In fact, however, it is beneath contempt, a level of existence so low as to be barely human. The enterprises we value most would shrivel to near nothingness in such a world: there would be no art or culture, no important public works, little technology and science-above all, no real human fellowship, no caring, no sacrifice.[33] Perversely enough, in fact, all we have to add to a world like this is war, and we get a situation not at all unlike Hobbes's state of nature, the very antithesis of anything we could value. Clearly, says the theist, we wish more for ourselves than this. A life without challenge is a life without interest.

If theism is correct on these matters, then a God interested in creating the best of worlds cannot have as his top priority the maximization of creaturely pleasure. Rather, a significant part of the enterprise of creation itself ought to be the confrontation and defeat evil-an accomplishment far greater than merely guaranteeing the unperturbed pleasure of all. And if human beings are created in God's image, and called to friendship with him, it is to be expected that they will have an important share in this enterprise. The central role in every human life of the struggle against evil bears this out. The battle is fought within each of us: the foremost challenge we face is that posed by our own sinfulness, which is overcome when we acknowledge that control of our destiny lies finally with God, and give up our false claim to ourselves. But for believers that is by no means the end of the matter. In the wake of repentance there should occur a gradual transformation of the individual, in which the damage wrought by sin is repaired, and the character traits appropriate for friendship with God are nourished. Remorse, anger and bitterness have to be replaced by gratitude, peace and hope; attitudes of failure must be supplanted by a sense of worth;

rationalization has to give way to self-understanding. Above all, the believer has to develop such virtues as humility, patience, courage, and concern for others-to give up selfishness in favor of charity. Hick calls this process "soul-making."[34] In it, the individual is transformed into a being suited for full friendship with God, because through the achievement of virtue he is made over into God's likeness. And much of the process takes place through our learning to deal with natural evil, with pain, sorrow and deprivation, in ourselves and others. By having to cope with our own suffering, we develop peace, humility, perseverance, and trust in God. We also learn sympathy for others who suffer, and by working to improve their lot we establish mercy and justice, in ourselves and in society. Indeed, much of human fellowship and solidarity is founded upon the support and comfort we lend to each other in times of need, and in the common enterprises by which we seek to secure ourselves and one another against the depredations of natural evil.

According to soul-making theodicy, then, by undergoing the soul-making process we develop the traits required for true friendship with God, in the only way that is suitable for humans. Some might object that God could have created virtuous people without their having to go through the troubles that afflict our present existence, that dispositions to good behavior need not be established through suffering.[35] Theists can respond, though, that this objection fails to grasp the nature of soul-making. Human virtues are not mere behavioral dispositions, of the kind found in the inanimate world. There are, no doubt, natural dispositions of patience, courage, kindness and the like-behavioral propensities we are born with, and that vary in strength from one individual to another. But these are not what we have in mind when we speak of moral virtue in the proper sense. True virtue has to be tested and refined. Someone with the virtue of patience must have tasted affliction and disappointment, and seen things through; the courageous person has to have endured danger and risk; the compassionate must have struggled with temptation, sorrow and hardship. The point of such experiences is not merely to strengthen our tendency to act rightly. Virtue is much more than an abiding behavioral propensity. It is a matter of practical wisdom. It requires that we know trial and suffering, and human weakness in the face of them, in the only way they truly can be known: through experience. Suffering, like sin, cannot be understood in the abstract. Only first hand awareness of the world's pain enables us to comprehend fully the options for good and ill in the situations we face, to judge correctly what action is called for, and to perform it with an attitude of humble submission to God, and loving concern for others. In short, true virtue requires knowledge of good and evil-not just as they are manifested in our own struggle with sin, but as they are played out in the travail of the whole world. As we gain this knowledge, we become more suited for God's friendship; indeed, the process of gaining it is the beginning of the friendship. For to address virtuously the hardships of life is not only to improve ourselves; it is to take up the role God has planned for us in the crucial creative enterprise of overcoming natural evil.

10. Suffering and Defeasibility

Soul-making, according to its defenders, is not possible except through the experience of suffering. Because this is so, and because a world in which humans are brought to spiritual maturity through this process is incomparably better than a hedonistic paradise, there is every reason to expect that a perfectly good and loving God would create a world in which there is suffering. Still, the opponent may object that

this answer is at best incomplete. For, he will argue, not all of the suffering of the world enters into soul-making. Consider again the case that was mentioned earlier, of the fawn caught in a forest fire. By and large, the sufferings of lower animals pass without even being remarked by rational beings, and seem to serve no purpose whatever. Even among humans, intense suffering is often followed simply by death, and contributes to no apparent moral development. Or, it may simply be that a person dies suddenly. What end of soul-making does that serve? And in any case, the complaint continues, surely the sheer *amount* of natural evil that exists in the world is incommensurate with the purposes described. In much of human pain and hardship we see little or nothing of the heroic, but only misery. Virtue is a fine thing, but could not God have contrived to purchase it less expensively?

It is difficult for the theist to give a fully satisfying answer at this point. Perhaps the best strategy is to invoke again the concept of defeasibility. For a theodicy that emphasizes that notion, God's full purpose in creating a world that includes pain and affliction includes more than the spiritual maturation of his creatures. Indeed, that effect is only concomitant to the objective that is first and foremost: that evil be defeated. We should expect, therefore, that evil will be found in the world to such a degree and in such variety as best to serve this overarching purpose. If anything less were so-if God, as creator, should shrink from some evil as too diabolical to be overcome, or too bitter to be endured-he would already have fled the field, and the battle would be lost before it had begun. But as to the actual degree and diversity of evil necessary for its defeat, that is very difficult for humans to judge. Our perspective on creation is vastly incomplete, and in any case we have no reason to expect to be privy to God's purposes regarding each detail of creation-especially, as we are about to see, when it comes to suffering. Still, some helpful points are available to the theist.

First, as regards the claim that there is too much evil, or that much of it serves no purpose, it is not obvious that each instance of suffering must be defeated separately from all others, or in the experience of the individual who endures it. The death of another can be as much a reminder to me of my finitude as my own impending death, sudden or lingering. The sufferings of others-even of lower animals-can be effective in arousing me to works of mercy and charity. Indeed, while particular acts of compassion must perforce be directed toward this or that specific instance of suffering, the attitude of compassion is not. Its object is *all* suffering, even suffering of which none but the sufferer will ever be specifically aware; and compassion can be awakened and reinforced by the very realization that much suffering goes unnoticed and unrequited. The same goes for other virtues. We may be prompted to greater efforts to secure justice in the world precisely because we know that much injustice is never redressed; we may seek to accomplish some difficult goal for which others suffered without success, and in whose memory we want to see it attained. One of the benefits of evil that seems unrequited, then, is that it elicits greater effort to deal with those ills we can address, and greater urgency to assist the forgotten. In this sense, at least, there is no such thing as suffering that serves no purpose.

A second important point concerns the *way* in which suffering is defeated in the process of soul-making. It is not simply that it is caught up in a larger process that is very good. That would be compatible with suffering merely being outweighed in the larger process, or with it serving only as a causal means to the achievement of virtue-neither of which is enough to secure its defeat. Rather, suffering is addressed in the process of soul-making and, as it were, refuted. To see how this occurs, we need to understand the nature

of suffering. It is rarely a matter of sheer physical pain, and even when it is, we are often quite prepared to bear it. A distance runner might endure a lot of pain, or a student considerable hardship, in pursuit of their goals. Yet both might maintain an optimistic spirit, and even deny they were really suffering. True suffering occurs when reason is left groping, and hope is called into question. We suffer when pain seems too great to bear and to serve no commensurate end: when the loss of a loved one leaves us dazed, empty and alone; when hateful assaults leave us feeling wounded and violated; when we are distressed by disease, or the decline of old age. Experiences like these tend to crowd all else out of our consciousness. They make us feel dismayed, vulnerable and incomplete; they make our projects appear trivial, our ambitions unreachable. Above all, the experience undermines our confidence in the essential goodness of the world, and our hope that all will be well. Indeed, what suffering does is to raise for each of us, in a way mere argument cannot, the problem of evil-and with it the inevitable temptation to sullenness, self-pity, and enmity toward whatever God there may be. But when we face the problem, and work through suffering, it is defeated. The defeat can manifest itself in many ways. Almost always, our capacity to endure future hardships, and to comfort others in theirs, is increased. We may come to see more accurately our place in the universe, to deepen our devotion to God, to resolve to assist in attacking the sources of suffering, in human wrongdoing as well as the vagaries of nature. In all of this, the theist may argue, natural evil is defeated: the very experience that threatens to overwhelm confidence in the good becomes the indispensable foundation for attitudes of character that serve to diminish its effects and aim at wiping it out. Above all, however, suffering is defeated in the simple fact that it is borne with good grace-that we refuse to submit to the temptation to descend into repining and bitterness, and resolve instead to continue in hope. Much of the heroism of those who suffer lies simply in this: that they strive to go on-something even a fawn can do.

The problem of suffering is not just an intellectual challenge, but a moral one as well. Evil calls for a certain reaction on our part, a reaction of striving, and it is defeated when that reaction occurs. It made be protested that this reaction is available only to believers, and hence that this approach to the problem of evil begs the question. That is not true. The theist is not required to produce a theodicy that will work even if there is no God, only one that will work if there is. And in any case, there seems to be no reason to think nonbelievers are precluded from participating in the defeat of evil. They can and do gain from suffering much as believers do-even to the point of reacting to it with hope in the final goodness of things, and with reverence for any source it may have, whatever its nature. It does have to be admitted, of course, that particular instances of pain and misery do not always meet with a positive response in the sufferer. There may not be sufficient time, and when there is the individual may lack the intelligence or understanding to react in ways we would recognize. Where we do understand the reaction, there may be a mix between good and bad manifestations of character. And of course there are cases where natural evil is borne with anything but good will-with furious anger, or morose despair. Faced with this reality, the theist can only point out what was mentioned above, that the evils which that befall some can and do work to encourage virtue in others, and this can occur by negative example also. If this seems insufficient, the theist can argue that in a world where each an every instance of evil was thoroughly and obviously defeated-so that a perfectly satisfying response to opponents of theism would always be available-an important evil would be missing. It is essential to the challenge of evil that it frequently appears gratuitous, that there seems to be too much of it, that as far as we can see, it often goes unaddressed. Anything less could not bring out the best in us. And then we would be far less suited to

God's friendship, and this world would be far less than is needed for it to be a creation worthy of God: the best of all possible worlds.

11.Conclusion

The hallmark of the traditional free will defense is its fastidiousness: it seeks to distance God from as much evil as possible, so that his goodness will not be tainted by it. The God of the Judeo-Christian tradition is not so fastidious. He is active in all our deeds, turning our hearts where he wills (*Prov*. 21:1), and working in us to will and to do as he pleases. Part of his purpose in this, the tradition holds, is that we be creatures with the moral authenticity that can only come with free will. The inevitable accompaniment, however, is that we sin. God does not will this for its own sake, but if God's providence is complete he does will for us the independence that amounts to our rebellion, for it is indispensable to his purpose. The question the tradition faces is whether God's providence can be complete here, whether he can have full sovereignty if we are truly free. The second focus of concern is the fact of suffering, which also falls under God's will. According to theodicies that emphasize soul-making and defeasibility, this is not because God is malevolent, but so that we can share with him the knowledge that evil is creation's enemy, and partake in the glory of its defeat. The scriptural God evinces no fear that he will be tainted by any of this, nor does he distance himself from evil in any way. On the contrary: even after Adam's sin God remains fully engaged with humankind, sparing no effort to secure our rescue, and treating our suffering with healing concern and compassion. In the Christian tradition, he is even willing to send his Son to bear our sorrows with us, and to be sacrificed so that we may again find acceptance with God in repentance. The fallenness of creation is not, then, an object of heavenly disdain, and for defenders of divine providence it is not cause for philosophical disappointment. Rather, they hold, the task of overcoming evil is central to the creative enterprise. We sin and suffer because God is out to defeat sin and suffering, and to see that all who are ordained to share in the victory do so. The theist is forced to admit, however, that we do not always understand in detail how this occurs. In that respect, at least, any theodicy has to be incomplete.

13. Luis de Molina, *On Divine Foreknowledge: Part IV of the Concordia*, tr. Alfred J. Freddoso (Ithaca,

New York: Cornell University Press, 1988). The Molinist view receives a thorough and careful defense from Thomas Flint in his *Divine Providence* (op. cit.), on which the present discussion is based.

14. Molina attributes three kinds of knowledge to God. *Natural* knowledge consists of logical and conceptual truths-e.g., that no bachelor is married-which are recognized by God as a matter of his essential nature. *Free* knowledge consists of contingent truths that are settled by God's will as creator-e.g., that there are tigers. Middle knowledge is so named because it falls between these two. The truths of which it is composed are, like those of free knowledge, contingent; but like natural knowledge they are held to be settled independently of God's will.

15. Flint, *Divine Providence*, pp. 37-41.

16. *Ibid*., p. 71.

17. That God could not know counterfactuals of freedom independently of his creative decisions is argued by Timothy O'Connor in "The Impossibility of Middle Knowledge," *Philosophical Studies* 66 (1992), 139-66.

Jonathan Edwards

Jonathan Edwards (1703-1758) is widely acknowledged to be America's most important and original philosophical theologian. His work as a whole is an expression of two themes -- the absolute sovereignty of God and the beauty of God's holiness. The first is articulated in Edwards' defense of theological determinism, in a doctrine of occasionalism, and in his insistence that physical objects are only collections of sensible "ideas" while finite minds are mere assemblages of "thoughts" or "perceptions." As the only real cause or substance underlying physical and mental phenomena, God is "being in general," the "sum of all being."

Edwards' second theme is articulated in accounts of God's end in creation, and of the nature of true virtue and true beauty. God creates in order to manifest a holiness which consists in a benevolence which alone is truly beautiful. Genuine human virtue is an imitation of divine benevolence and all finite beauty is an image of divine loveliness. True virtue is needed to discern this beauty, however, and to reason rightly about "divine things."

Edwards' projected *History of Redemption* would have drawn these themes together, for it is in his redemptive work in history that God's sovereignty, holiness, and beauty are most clearly exhibited.

1. Life

Edwards was born into a family of prominent Congregational ministers in East Windsor, Connecticut in 1703. In 1716 Edwards enrolled in Yale where he read Newton and Locke, and began "Notes on the Mind" and "Notes on Natural Science." Locke's influence on his epistemology, philosophy of language, and philosophical psychology was profound. Edwards' metaphysics, however, appears more strongly influenced by Malebranche and, to a lesser extent, the Cambridge Platonists, and bears little resemblance to Locke's. After briefly serving congregations in New York and Bolton, Connecticut, Edwards returned to Yale where he completed his Masters of Arts degree and became senior tutor in 1724. In 1725, the church in Northampton chose Edwards to succeed his grandfather, Solomon Stoddard -- the so-called "pope of the Connecticut valley." The most notable events of his tenure were the revivals of 1734 and 1740-41, the latter of which came to be known as the Great Awakening. Edwards' defense of the revivals and criticisms of its excesses culminated in his first major treatise, the *Religious Affections* (1746). Worsening relations with his congregation came to a head in a dispute over qualifications for church membership. Rejecting the less rigorous standards of his grandfather, Edwards insisted on a public profession of saving faith based on the candidate's religious experiences as a qualification not only for Holy Communion but also for church membership. He was dismissed in 1750 by a margin of one vote. After refusing invitations to pulpits in North America and Scotland, Edwards retreated to the Indian mission at Stockbridge where he had charge of two difficult congregations, supervised a boarding school for Indian boys, and completed his last major works -- *Freedom of the Will* (1754), *Original Sin* (1758), *End of Creation*, and *True Virtue* (both published posthumously in 1765). Edwards accepted an appointment as President of the College of New Jersey (now Princeton) in 1757. He died from complications arising from a smallpox inoculation on March 22, 1758, less than five weeks after his inauguration. Edwards' published works were primarily designed to defend the Puritan version of Calvinist orthodoxy and his influence on Congregational and Presbyterian theology was profound. His extensive notebooks reveal an interest in philosophical problems for their own sake, however, and his deployment of philosophical arguments in his private papers and published works are both sophisticated and frequently original.

2. Metaphysics

2.1 Theological Determinism

Edwards believed that indeterminism is incompatible with our dependence on God and hence with his sovereignty. If our responses to God's grace are contra-causally free, then our salvation depends partly on us and God's sovereignty isn't "absolute and universal." *Freedom of the Will* defends theological determinism. Edwards begins by attempting to show that libertarianism is incoherent. For example, he argues that by 'self-determination' the libertarian must mean either that one's actions including one's acts

of willing are preceded by an act of free will or that one's acts of will lack sufficient causes. The first leads to an infinite regress while the second implies that acts of will happen accidentally and hence can't make someone "better or worse, any more than a tree is better than other trees because it oftener happens to be lit upon by a swan or nightingale; or a rock more vicious than other rocks, because rattlesnakes have happened oftener to crawl over it." (*Freedom of the Will*, 1754; Edwards 1957-, vol. 1, 327) On the second alternative, acts of choosing (volitions) are neither chosen by us nor determined by reasons or our character or by other states of the soul. But if they are not, then they aren't truly ours and we cannot be held responsible for them. Edwards also argues that libertarianism is inconsistent with ordinary moral concepts. If, for example, the necessity of sinning wholly excuses, then a bias to sin should partially excuse. But it doesn't; a person who acts from settled habits of maliciousness is deemed "so much the more worthy to be detested and condemned." (*Freedom of the Will*, 1754; Edwards 1957-, vol. 1, 360) Since libertarianism implies that necessity excuses, it is inconsistent with the way we attribute blame.

In Edwards' opinion, libertarianism's specious aura of plausibility is grounded in a systematic confusion of "philosophical" and "vulgar" (ordinary) usage. For example, in ordinary usage something (e.g., remaining seated) is said to be "necessary to us...when we can't help it, let us do what we will." *(Freedom of the Will*, 1754; Edwards 1957-, vol. 1, 150) Causal necessity doesn't entail "vulgar necessity," however. Ingrained habits, deeply felt resentment, and the like may causally necessitate a malicious action. It doesn't follow that the agent wouldn't have refrained from acting maliciously if she had chosen not to act maliciously. Hence, the fact that she was causally unable to act other than she did does not imply that she was unable to do so in the "vulgar" or ordinary sense. Libertarians are therefore mistaken in thinking that because vulgar necessity excuses, so does causal necessity. Again, 'freedom' or 'liberty' in common speech refer only to "that power and opportunity for one to do and conduct as he will, or according to his choice," and contains no reference to the "cause or original" of the act of will. (*Freedom of* the *Will*, 1754; Edwards 1957-vol. 1, 163-64) Hence, that liberty in the ordinary sense is essential to moral agency does not entail that contra-causal freedom is. It is also important to note that action in the ordinary sense is "some motion or exertion of power, that is voluntary, or that is the *effect* of the will...[the term is] most commonly used to signify outward actions." *(Freedom of the Will*, 1754; Edwards 1957-, vol. 1, 346) Improperly extending the term 'action' to movements of the will has led some libertarians to conclude that since external behavior must be preceded by an act of will to be voluntary, and an appropriate object of moral appraisal, so too must acts of will. A consequence is the libertarian's misleading talk of the will's self-determination.

Edwards' principle reasons *for* theological determinism are God's sovereignty, the principle of sufficient reason (which requires that everything that begins to be have a complete cause), the nature of motivation, and God's foreknowledge. The latter two are discussed at length.

The argument from motivation depends upon Edwards' identification of willing or choosing with one's strongest inclination or preference. Since choosing just *is* a prevailing inclination, it is logically impossible to choose in the absence of a prevailing motive. If there is a prevailing motive, however, then the will is necessarily determined by it, for if the will were to choose contrary to a prevailing motive, the agent would have two opposed preponderant inclinations at the same time. All choices, therefore, are necessarily determined.

Edwards' most impressive arguments from divine foreknowledge are based on the impossibility of knowing future contingents and on the necessity of the past. One knows p only if one has evidence for it, and evidence "must be one of...two sorts, either *self-evidence* or *proof*." Propositions about future contingents can't be self-evident, however, because the states of affairs they represent are neither present to the mind nor necessary. But they can't be proved either, for if the state of affairs expressed by the proposition is genuinely contingent, "there is nothing now existent with which the future existence of the contingent event is [necessarily] connected." Future contingents are thus necessarily unknowable. (*Freedom of the Will*, 1754; Edwards 1957-, vol. 1, 259) Since God's knowledge of the future is comprehensive, it follows that no future event (and so no future human action) is genuinely contingent.

The conclusion also follows from the necessity of the past. Suppose I make a decision D at time t. Since God is omniscient, he has always believed that D occurs at t. Since he can't be mistaken, God's believing at some earlier time t-n that D occurs at t entails that D occurs at t. But God's forebelief is past in relation to t and is therefore "now necessary" in the sense that nothing done at t can alter it. What is entailed by a necessary fact is itself necessary, however. Therefore, D could not fail to occur at t. Nor can one evade this conclusion by appealing to God's timelessness as some do. For even if God's 'forebeliefs' are timeless and so don't precede the events they are about, divinely inspired prophecies are not. Yet divinely inspired prophecies, too, are necessarily connected with the human actions they foretell and they are clearly past (and hence necessary) in relation to them.

Necessity is consistent with moral responsibility, however. We are said to be responsible for our actions when we act as we choose and determinism does not deny that our actions often spring from our choices. Nor is necessity incompatible with praise and blame. Even though God and Christ necessarily act for the best, their actions are eminently praiseworthy.

It is worth noting that the aim of Edwards' philosophically sophisticated arguments is theological. He saw that "if modern divines...can maintain their peculiar notion of freedom, consisting in the *self-determining power* of the will, as necessary to moral agency..., then they have an impregnable castle, to which they may repair, and remain invincible, in all the controversies they have with the reformed divines concerning *original sin*, the *sovereignty* of grace, election..., and other principles of like kind." (*Freedom of the Will*, 1754; Edwards 1957-, vol. 3, 376) Edwards recognizes that "modern divines" pretend that doctrines like these undermine "the very foundation of all religion and morality. (*Freedom of the Will*, 1754; Edwards 1957, vol. 1, 422) *Freedom of the Will* concludes by arguing that, on the contrary, they do a much better job of supporting them.

2.2 Occasionalism, Idealism, Mental Phenomenalism, and Views on Identity

Edwards' occasionalism, idealism, and mental phenomenalism provide a philosophical interpretation of God's absolute sovereignty: God is the only real cause and the only true substance.

Edwards implicitly distinguishes between a real or true cause and a cause in the ordinary or "vulgar" sense. The latter is "that, after or upon the existence of which, or the existence of it after such a manner, the existence of another thing follows." ("The Mind," no. 26; Edwards 1957-, vol. 6, 350) Vulgar causes aren't real causes, however. In the first place, so-called second causes are spatially or temporally distinct from their effects, and "no [real] cause can produce effects in a time and place on which itself is not." (*Original Sin*, 1758; Edwards 1957-, vol. 3, 400) In the second, real causes necessitate their effects and second causes do not. "It don't at all necessarily follow," for example, "that because there was...color, or resistance,...or thought, or any other dependent thing at the last moment, that therefore there shall be the like at the next." *(Original Sin*, 1758; Edwards 1957-, vol. 3, 404). Finally, if second causes were real causes they would be sufficient to produce their effects. If they were sufficient, however, then God's activity would be redundant and it is not. Unlike second causes, God's causal activity meets all three conditions. Since God is not in time or space, there is no temporal or spatial separation between his activity and its effects. Since God is essentially omnipotent, his will is necessarily effective; it is logically impossible for him to will s and s not take place. The third condition is also met. Because God is omnipotent he doesn't need the cooperation of other causal powers to produce his effects. And because sovereignty belongs to him alone he doesn't share his causal power with others. God's decrees are thus fully sufficient for their effects. God alone, then, is the only real cause. Vulgar causes (e.g., heating water) are simply the occasions upon which God produces effects (e.g., the water's boiling) according to "methods and laws" which express his customary manner of acting.

In an early paper ("Of Atoms") Edwards pointed out that the concept of a material substance is the concept of something subsisting by itself, standing "underneath," and keeping "up solidity and all other [physical] properties." (Edwards 1957-, vol. 6, 215) He then argued that God alone meets these conditions, and concluded that if the concept of material substance refers to anything, it refers to God's causal activity.

Edwards also thought that "nothing has existence any where else...but either in created or uncreated consciousness." It follows that "the material universe exists only in the mind;" "the existence of all corporeal things is only ideas." ("Of Being," "The Mind," no. 51, and "Miscellanies," no. 179; Edwards 1957, vol. 6, 204, 368, and vol. 13, 327)

Edwards' arguments for idealism are similar to (but apparently uninfluenced by) Berkeley's. One of the best examples occurs in "The Mind," no. 27. Edwards first argues that the idea of a body can be resolved into ideas of color and resistance. Figure, for example, is the termination of color or resistance. Solidity *is* resistance, while motion is "the communication of this resistance from space to space." "Every knowing philosopher" agrees that colors exist only in minds. 'Resistance' refers either to instances in which one body resists another or to a power, namely, a body's disposition to resist other bodies. The first is a mode or property of ideas; it is ideas which are "resisted...move and stop, and rebound." For example, our observation of a billiard ball's ricocheting from the cushion can be resolved into impressions of a particular configuration of color and figure (the billiard ball) moving closer to another (the cushion), touching it, and then moving away from it. The power of resistance is no more than a divine "establishment," namely, "the constant law or method" of "the actual exertion of God's power" producing instances of resistance. So *instances* of resistance are qualities of ideas and the *power* of resistance is a

stable divine intention to act in certain ways. Resistance, therefore, exists only in relation to minds. Since the idea of a body can be reduced to ideas of color and resistance, and color and resistance have only mental existence, "the world is...an ideal one." (Edwards 1957-, vol. 6, 350-51)

Edwards' mental phenomenalism is a natural extension of his occasionalism and views on substance. If God is the only real cause of spatio-temporal phenomena, he is the only real cause of "thoughts" or "perceptions." If a substance is what "subsists by itself," "stands underneath," and "keeps up" a set of properties, then a mental substance can only be what subsists by itself, stands underneath, and keeps up mental properties. It follows that the concept of mental substance either denotes nothing or refers to God's causal activity. "What we call spirit," then, "is nothing but a composition and series of perceptions [mental events]...connected by...laws." ("Notes on Knowledge and Existence"; Edwards 1957-, vol. 6, 398)

Mental and physical substance are thus identical with God's causal production of the mental events constituting minds and the sensible ideas or "sensations" which constitute bodies "according to...methods and laws " which he has freely established. ("The Mind," no. 13; Edwards 1957-, vol. 6, 344) God is thus the only true substance as well as the only true cause.

God's sovereignty also extends to criteria of identity. "Species" (kinds or natures) are the ways we classify things. But our classifications depend on our needs and interests, and the character of the world we live in. Hence, in determining every feature of the spatio-temporal world, God has determined how things will be classified, that is, what counts as a "species" or kind. Since a thing's criteria of identity are determined by its nature or kind, God is their ultimate ground. In short, laws determine kinds and kinds determine criteria of identity. In determining laws God has therefore determined criteria of identity. (One implication is that God can so arrange things that Adam and his posterity count as one thing for purposes of punishment and reward.)

2.3 God as Being in General

God is "being in general." He "is the sum of all being and there is no being without His being. All things are in Him and He in all." ("Miscellanies," no. 880; Edwards 1955, 87) Edwards appears to have borrowed the phrase "being in general" from Malebranche. What does he mean by it?

He does not mean that God is the power of being or being as such as earlier commentators like Clyde Holbrook and Douglas Elwood have suggested. God is neither a power nor a universal but a concrete entity or substance -- a necessarily existing "intelligent willing agent such as our souls, only without our imperfections, and not some inconceivable, unintelligent, necessary agent." ("Miscellanies," no. 383; Edwards 1957-, vol. 13, 452)

True Virtue associates being with capacity or power, and asserts that "degree of existence" is a function of "greater capacity or power," of having "every faculty and every positive quality in an higher degree. An *archangel* must be supposed to have more existence, and to be every way further removed from

nonentity than a *worm* or a *flea*." (*True Virtue*, 1765; Edwards 1957-, vol. 8, 546) Miscellany 94 identifies perfect entity and perfect activity. "God is a pure act...because that which acts perfectly is all act, and nothing but act. There is an image of this in created beings that approach to perfect action." Thus, "the saints of heaven are all transfigured into love. dissolved into joy, become activity itself, changed into mere ecstasy." (Edwards 1957-, vol. 13, 260f.) "An Essay on the Trinity" argues that God’s essence is a love which subsists "in pure act and perfect energy," his holy will or activity. (Edwards 1971, 99-100, 110-11) "Of Being" and "The Mind," no. 45 identify being with consciousness. "Perceiving being only is properly being." (Edwards 1957-, vol. 6, 363) Although Edwards never systematically developed or integrated these scattered observations, their drift is toward the identification of being with mind in act, and of degree of being with degree of mind or consciousness and the comparative perfection of the activity in which it is engaged. God’s consciousness and power are unlimited, and his activity is perfect. His being is therefore unlimited.

Why, though, is God being in general? Because finite beings are absolutely and immediately dependent upon him for both their being and properties. Indeed, as the only true substance and only true cause, created beings are no more than God’s "shadows" or "images." (While "particular minds" deliberate and choose, and so possess a kind of agency, they lack real power and are thus no more than images of divine agency. Because they lack not only power but also consciousness and will, bodies are even further removed from real agency and hence are, as Edwards says, mere shadows of being.) As the only true substance and only true cause, God is the "head" of the system of beings, its "chief part," an absolute sovereign whose power and perfection are so great that "all other beings are as nothing to him, and all other excellency...as nothing and less than nothing,...in comparison of his." (*End of Creation*, 1765; Edwards 1957-, vol. 8, 451) "The whole system of created beings, in comparison of Him, is as the light dust of the balance." ("Miscellanies," no. 1208; Edwards 1955, 142) ‘Being in general,’ then, refers to the system of beings -- primarily to God but to "particular beings," too, in so far as they depend upon and more or less adequately reflect him.

The claim that God is the only real substance, the "proper entity" of things, has led to accusations of pantheism. Students of Edwards have responded by insisting on a distinction in Edwards between God and creatures. The distinction is real but insufficient to refute charges of pantheism. For, historically, pantheisms do not identify the divine with nature as such but, rather, with nature’s substance or essence or inner being or power. Natural phenomena aren’t identical with the divine. They are its modes or properties or parts. Edwards clearly believes that God is the world’s real substance. However, the sense of his assertion is very different from that of the pantheists. In claiming that God is the world’s substance Edwards means that God’s decrees are the only cause of an entity’s being and characteristics. He isn’t a pantheist because the relation between God and the world is construed as a relation between a creative volition and its immediate effects. Edwards’ model is not a whole and its parts, or a substance (a bearer of properties) and its properties, or an essence and its accidents, but agent causality.

2.4 God’s End in Creation

Edwards never doubted that God’s end is himself. Since true virtue consists in benevolence to being and

"complacence" or delight in moral excellence, and since God is the "chief part" of being and the fount of all excellence, a truly virtuous agent "must necessarily have a supreme love to God, both of benevolence and complacence." (*True Virtue,* 1765; Edwards 1957-, vol. 8, 551) It follows that *God's* rectitude and holiness "chiefly consists in a respect or regard to himself, infinitely above his regard to all other beings" and that, as a consequence, his works must be "so wrought as to show this supreme respect to himself." (*End of Creation*, 1765; Edwards 1957-, vol. 8, 422) God's ultimate aim in all his works must therefore be himself. Edwards concludes that he creates the world for his own glory. But Edwards also believed that because the essence of goodness is to communicate good for it own sake, "happiness is the end of the creation." ("Miscellanies," no. 3; Edwards 1957-, vol. 13, 199)

End of Creation reconciles these claims. God's glory is defined as "the emanation and true external expression of God's internal glory and fullness." It includes (1) "the exercise of God's perfections to produce a proper effect," (2) "the manifestation of his internal glory to created understandings," (3) "the communication of the infinite fullness of God to the creature," and (4) "the creature's high esteem of God, love to God, and complacence and joy in God; and the proper exercises and expressions of these." (*End of Creation*, 1765; Edwards 1957-, vol. 8, 527)

There is no ontological distinction between the first and third "parts" of God's glory since the principal effect of God's exercising his perfections is "his fullness communicated." Furthermore, the third part includes the second and fourth. For God's internal fullness or glory is the "fullness of his understanding consisting in his knowledge" of himself "and the fullness of his will consisting in his virtue and happiness." His "external glory...consists in the communication of these," i. e., in bringing it about that "particular minds" know and love God, and delight in him. The four "parts" are thus "one thing, in a variety of views and relations." (*End of Creation*, 1765; Edwards 1957-, vol. 8, 527)

In pursuing his own glory, God thus takes both himself *and* the creature's good as ultimate aims. Happiness consists in the knowledge and love of God, and joy in him. The creature's happiness is an ultimate end because it is *included* in God's ultimate end, namely, the communication of his internal glory "ad extra;" rather than being a means to God's glory, it is part of it.

An apparent consequence is that God *must* create a world to display his glory. *End of Creation* contends both that God's perfections include "a propensity of nature to diffuse of his own fullness" and that it isn't "possible for him to be hindered in the exercise of his goodness and his other perfections in their proper effect." (*End of Creation*, 1765; Edwards 1957-, vol. 8, 447) It follows that God must diffuse his own fullness, i. e., God must create. Edwards also appears committed to the claim that God necessarily creates *this* world (call it w*). God necessarily does what is "fittest and best." It is thus necessarily true that God creates the best possible world. Now God has created w*. Hence, w* is the best possible world. 'Being the best possible world' is an essential property of whatever world has it, however. It is therefore necessarily true that w* is the best possible world. It follows that it is necessarily true that God creates w*.

Whether Edwards was aware of these consequences is uncertain. The two most common objections to them, however, -- that they imply that there isn't any real contingency and that God isn't free -- would

not have troubled him. For Edwards thought that our world displays neither contra-causal freedom nor real indeterminacy. He also believed that moral agency and freedom are compatible with metaphysical necessity. God can only do what is "fittest and best." He is nevertheless free in the sense that he is aware of alternatives (the array of possible worlds), has the ability (i. e., the power and "skill") to actualize any of them, is neither forced, constrained nor influenced by any other being, and does precisely what he wishes. Edwards believes that this is the only kind of freedom that is either relevant to moral agency or worth having.

3. Value Theory

3.1 Ethics

True virtue aims at the good of being in general and therefore also prizes the disposition that promotes it. Truly virtuous people thus love two things -- being and benevolence. They not only value benevolence because it promotes the general good, however; they also "relish" or delight in it for its own sake. Hence, while virtue "most essentially consists in benevolence to being" (*True Virtue*, 1765; Edwards 1957-, vol. 8, 540), in a wider sense it includes not only benevolence but also "complacence" in benevolence's intrinsic excellence or beauty.

God, though, "is infinitely the greatest being," and "infinitely the most beautiful and excellent." True virtue thus principally consists "in a supreme love to God, both of benevolence and complacence." (*True Virtue*, 1765; Edwards 1957-, vol. 8, 550-51) It follows that "a determination of mind to union and benevolence to a *particular person* or *private system* [whether one's self, one's family, one's nation, or even humanity], which is but a small part of the universal system of being...is not of the nature of true virtue" unless it is dependent on or "subordinate to, benevolence to *Being in general*." (*True Virtue*, 1765; Edwards 1957-, vol. 8, 554)

One of the principal concerns of Shaftesbury, Hutcheson, et al., was to refute the contention that action is always motivated by self-love. Edwards' attitude toward these attempts is ambivalent. On the one hand, he denies that the *truly* benevolent are motivated by self-love. On the other, Edwards argues (against, e.g., Hutcheson) that most conscientious and other regarding behavior is, indeed, a form of self-love and that, in any case, acts motivated by rational self-love, conscience, or natural other regarding instincts such as parental affection or pity aren't genuinely virtuous.

Conscience, for instance, is the product of a power of placing ourselves in the situation of others (which is needed for any sort of mutual understanding), a sense of the natural fitness of certain responses (injury and punishment or disapproval, benefit and reward or approval), and self-love. Placing ourselves in the situation of those we have injured, we recognize that being treated in that way would not merely anger us but seem unfitting or undeserved, and that we are therefore inconsistent in approving of our treating others in ways we would not wish to be treated ourselves. The result is a sense of "inconsistence" or "self-opposition" between feelings of approval and disapproval toward the same action. This makes us

"uneasy" since "self-love implies an inclination to feel and act as one with ourselves." (*True Virtue*, 1765; Edwards 1957-, vol. 8, 589)

What, though, about instinctual other regarding impulses such as parental affection, "mutual affection between the sexes" (as distinct from simple sexual attraction), and pity? Edwards is inclined to think that all except pity are forms of self-love. The important point, however, is that even if they aren't, actions motivated by them aren't truly virtuous. To see why consider pity. If *truly* virtuous actions are motivated by benevolence to being in general, then actions motivated by other regarded impulses which are ultimately directed to "some particular persons or private system" aren't truly virtuous. (*True Virtue*, 1765; Edwards 1957-, vol. 8, 601) Now pity is directed to those in extreme distress whose suffering appears undeserved or excessive. Its object is therefore restricted to only part of being in general. Furthermore, since instinctual affections aren't "dependent" on "general benevolence," they are in potential conflict with it. Pity, for example, may motivate a judge to act unjustly.

We should not conclude that pity or other instinctual affections, or even rational self-love, are bad. Since they tend toward "the preservation of mankind and their comfortably subsisting in the world," things would be much worse without them. (*True Virtue*, 1765; Edwards 1957-, vol. 8, 600) Edwards point (like Kant's) is merely that their goodness isn't a truly moral goodness. The implication is nonetheless clear. Natural virtues are either tainted with self-love or fail to extend to being in general. They are therefore counterfeits or simulacra of true virtue. While they prompt us to promote the good of others, and to condemn vice, they fall infinitely "short of the extent of true virtuous benevolence, both in...nature and object." (*True Virtue*, 1765; Edwards 1957-, vol. 8, 609) Edwards concludes that true virtue is a supernatural gift.

3.2 Aesthetics

In Edwards' view, beauty or "excellency" "consists in the similarness of one being to another -- not merely equality and proportion, but any kind of similarness....This is an universal definition of excellency: The consent of being to being...". ("The Mind," no. 1; Edwards 1957-, vol. 6, 336) One who loves others, for instance, or actively desires their welfare, "agrees" with them or "consents" to them. Love's scope can be narrower or wider, however. Agreement or consent is "comprehensive" or "universal" only when directed towards being in general. Only true benevolence, therefore, is truly beautiful.

"Secondary" beauty is a mere "image" or "resemblance" of true beauty. It consists in "symmetry," "harmony," or "proportion," or "as Mr. Hutcheson" says, in "agreement of different things in form, manner, quantity, and visible end or design," i. e., in "regularity." The beauty of well-ordered societies, of "wisdom...consisting in the united tendency of thoughts, ideas, and particular volitions to one general purpose," of the natural fitness of actions and circumstances (having made a promise, for example, and keeping it), "of a building, of a flower, or of the rainbow" are examples. (*True Virtue*, 1765; Edwards 1957-, vol. 8, 561-62)

Since God's benevolence alone is perfect, he is the only thing that is (truly) beautiful without qualification. The fitness of God's dispensations, the harmony of his providential design, and so on, also exhibit the highest degree of secondary beauty. God is thus "infinitely the most beautiful and excellent," the measure of both primary and secondary beauty. Moreover, he is the "foundation and fountain of all beauty." "All the beauty to be found throughout the whole creation is...the reflection of the diffused beams of that being who hath an infinite fullness of brightness and glory." (*True Virtue*, 1765; Edwards 1957-, vol. 8, 550-51) And God's world is indeed *saturated* with beauty -- not only the "harmony of sounds, and the beauties of nature" (which bear the greatest resemblance to true or primary beauty, and to which Edwards was especially sensitive) but also (and primarily) the beauty of the Gospel, of God's providential work in history, and of the saints (the elect). The saints alone, however, can discern true beauty.

4. Epistemology

4.1 A Sense of the Heart

Because their hearts have been regenerated by the indwelling of the Holy Spirit, the saints love being in general. Their love is the basis of a new "spiritual sense" whose "immediate object" is "the beauty of holiness" -- a "new simple idea" that can't "be produced by exalting, varying or compounding" ideas "which they had before," and that truly "represents" divine reality. (*Religious Affections*, 1746 and *True Virtue*, 1765; Edwards 1957-, vol. 2, 205, 260, and vol. 8, 622)

Edwards sometimes identifies true beauty with the pleasure that holy things evoke in people with spiritual "frames" or "tempers" or with the tendency they have to evoke it. At other times he identifies it with the consent of being to being, i.e., with true benevolence or holiness. His view appears to be this. True beauty is identical with benevolence or agreement in somewhat the same way in which water is identical with H_2O or heat with molecular motion. But benevolence is also the objective basis of a dispositional property, namely, a tendency to produce a new simple idea in the savingly converted. This idea is a delight or pleasure in being's consent to being which somehow "represents" or is a "perception" of it. Edwards' account of true beauty thus resembles some accounts of color or extension. Spiritual delight is a simple idea or sensation like our ideas of color or extension. The dispositional property is a power objects have to produce these ideas in our understandings. Benevolence is the objective configuration underlying this power and corresponds to the microstructure of bodies that underlie their tendency to excite ideas of color or extension in minds like ours. Like simple ideas of redness, say, or extension, the new spiritual sensation "represents" or is a "perception" of its object. Just as 'red' or 'extension' can refer to the idea, the power, or the physical configuration that is the basis of the power, so "true beauty" can refer to the spiritual sensation, to the relevant dispositional property, or to benevolence.

Edwards calls the new mode of spiritual understanding a "sense" because the apprehension of spiritual beauty is (1) non-inferential and (2) involuntary, and Edwards, like Hutcheson, associates sensation with immediacy and passivity. (3) It also involves relish or delight, and Edwards followed Locke and

Hutcheson in thinking that, like a feeling of tactual pressure or an impression of redness, being pleased or pained is a kind of sensation or perception. Finally, (4) the new mode of understanding is the source of a new simple idea, and Edwards shared Locke's and Hutcheson's conviction that simple ideas come "from experience."

The saints alone are in an epistemic position to discern truths of religion that are dependent on the "excellency of divine things. For example, a conviction of Christ's sufficiency as a mediator depends on an apprehension of his beauty and excellency. Or, again, one must see the beauty of holiness to appreciate the "hatefulness of sin," and thus be convinced of the justice of divine punishment and our inability to make restitution. The new sense also helps us grasp the truth of the gospel scheme as a whole. A conviction of its truth is an immediate inference from a perception of the beauty or splendor of what it depicts, namely, "God and Jesus Christ...the work of redemption, and the ways and works of God." (*A Divine and Supernatural Light*, 1734; Edwards 1957-, vol. 17, 413)

Edwards' defense of the objectivity of the new spiritual sense has four steps. (1) Benevolence agrees with the nature of things. The world is an interconnected system of minds and ideas in which the only true substance and cause is an infinite and omnipotent love. Human benevolence is thus an appropriate or fitting response to reality. (2) Benevolence is pleased by benevolence; it relishes it, or delights in it, for its own sake. Since benevolence is an appropriate response to reality, so too is benevolence's delight in benevolence. (3) But a delight in benevolence just is a perception of its spiritual beauty. It follows that (4) the redeemed's spiritual perceptions are veridical -- "representations" of something "besides what [is] in [their] own minds." (*True Virtue*, 1765; Edwards 1957-, vol. 8, 622)

4.2 Sanctified Reason

Edwards thinks that reason can prove that God exists, establish many of his attributes, discern our obligations to him, and mount a probable case for the credibility of scripture. But he also believes that grace is needed both to help the natural principles "against those things that tend to stupefy [them] and to hinder [their] free exercise," and to sanctify "the reasoning faculty and" assist "it to see the clear evidence there is of the truth of religion in rational arguments." ("Miscellanies," nos. 626, 628; Edwards 1957-, vol. 18, 155, 156f.)

His view is briefly this. "Actual ideas" are ideas that are lively, clear, and distinct. Thought has a tendency to substitute "signs" (i. e., words or images) for actual ideas. While this tendency is useful and normally quite harmless, it impedes reasoning when "we are at a loss concerning a connection or consequence [between ideas], or have a new inference to draw, or would see the force of some new argument." ("Miscellanies," no. 782; Edwards 1957-, vol. 18, 457) Since accurate reasoning about a subject matter requires attending to actual ideas of it, one can't accurately reason about religion if one lack the relevant actual ideas. To have an actual idea of God, for example, one must have actual ideas of the ideas that compose it. But most of us don't. Those parts of the idea of God that everyone has (ideas of knowledge, power, and justice, for instance) either aren't attended to or, if they are, fail to elicit the appropriate affective reaction. In addition, we can't fully understand ideas of affections which we haven't

experienced and so can’t properly understand God’s benevolence if we aren’t benevolent ourselves. And without the simple idea of true beauty, one can understand neither God’s holiness nor the facts that depend on it.

True benevolence remedies these deficiencies. Because the desires of the truly benevolent are properly ordered, they attend to ideas of religion and are suitably affected by the ideas of God’s attributes and activities that everyone has. (They fear his wrath, for example, and are grateful for his benefits.) Furthermore, they understand God’s benevolence because their own benevolence mirrors it. Finally, the truly benevolent delight in the benevolence in which holiness consists, i. e., they "perceive" or "taste" or "relish" its beauty. Edwards’ claim, then, is that to reason accurately about God one must have an actual idea of him, and to have that one must be truly benevolent. Right reasoning about religious matters requires right affections.

Edwards is an evidentialist. Rational religious beliefs are either properly basic or rest on good evidence. A belief that the gospel scheme exhibits true beauty is an example of the former. But most religious beliefs depend on evidence. Sometimes this evidence includes the idea of true beauty. Even when it does not, however, the right affections are needed to appreciate its force. In either case, only those with properly disposed hearts can read the evidence correctly.

5. The History of Redemption

The trustees of the College of New Jersey invited Edwards to become its third president in 1753. In his reply Edwards gave a number of reasons why he hesitated to accept their offer. Among these was the fear that doing so would interfere with the completion of "a great work" which he had long contemplated "which I call a *History of the Work of Redemption*, a body of divinity in an entire new method, being thrown into the form of an history; considering the affair of Christian theology, as the whole of it, in each part, stands in reference to the great work of redemption by Jesus Christ...." (Edwards 1957-, vol. 16, 727f.) Although Edwards’ project was aborted by his untimely death, it would undoubtedly have been based on a sermon series delivered in 1739 which traces the work of redemption "from the fall of man to the end of the world." The proposed history would have been the culmination of the project begun in *True Virtue* and *End of Creation*. For creation and providence are subordinate to a redemption which is itself subordinate only to God’s glory. The history of redemption is "the *summum* and *ultimum* of all the divine operations and decrees," the manifestation of God’s internal glory in time. (Edwards 1957-, vol. 16, 728) Edwards’ *History* would also have provided a fitting climax to his intellectual career as a whole. For it is in his work of redemption that God’s sovereignty, holiness, and splendor are most fully displayed.

It is doubtful, however, that Edwards’ work would have anticipated modern historiography as some claim. For one thing, the sermon series is essentially a *doctrinal* work. (The section on Christ’s earthly ministry, for instance, is a discussion of the incarnation and atonement, not a life of Jesus.) For another, Edwards’ sources include not only biblical and "profane" histories but biblical prophecy as well. Finally, Edwards doesn’t restrict himself to natural causes in explaining events but also appeals to divine decrees and typology.

Whatever novelty the sermon series possesses is literary and theological. It partly consists in the rich skein of images Edwards uses to connect the events of redemption history. These include the model of a river and its tributaries, a tree and its branches, the construction of a building, the conduct of war, and "a wheel," or "a machine composed of wheels" with its reminiscences both of Ezekiel's vision of the divine throne chariot and of clockwork. ("Images of Divine Things," no. 89; Edwards 1957-, vol. 11, 86) It also consists in Edwards' extension of typology, the practice of interpreting things, persons, or events (the "type") as symbols or prefigurations of future realities (the "antitype"). Protestant divines had tended to restrict typology to figures, actions, and objects in the Old Testament which in their view shadowed forth Christ as their antitype. Edwards interprets the New Testament typologically as well, arguing that relevant passages prefigure events in the church's later history. Most radically, Edwards construes nature typologically. (Whether this constitutes a step towards Emerson and Thoreau, as some claim, is a moot point.) Finally, Edwards' emphasis on the objective side of God's act of redemption is comparatively rare in a Puritanism which tended to stress the redemption's application to individual souls. (The subjective side is extensively treated in a number of works of the 1730's and 1740's, however, the most important of which is *Religious Affections*.)

(From Amos Bronson Alcott, *Ralph Waldo Emerson: An Estimate of His Character and Genius: In Prose and in Verse*, Boston: A. Williams and Co., 1882)

Ralph Waldo Emerson

An American essayist, poet, and popular philosopher, Ralph Waldo Emerson (1803-82) began his career as a Unitarian minister in Boston, but achieved worldwide fame as a lecturer and the author of such essays as "Self-Reliance," "History," "The Over-Soul," and "Fate." Drawing on English and German Romanticism, Neoplatonism, Kantianism, and Hinduism, Emerson developed a metaphysics of process, an epistemology of moods, and an "existentialist" ethics of self-improvement. He influenced generations of Americans, from his friend Henry David Thoreau to John Dewey, and in Europe, Friedrich Nietzsche, who takes up such Emersonian themes as power, fate, the uses of poetry and history, and the critique of Christianity.

1. Chronology of Emerson’s Life

1803, Born in Boston to William and Ruth Haskins Emerson.

1811, Father dies, probably of tuberculosis.

1812, Enters Boston Public Latin School

1817, Begins study at Harvard College: Greek, Latin, History, Rhetoric.

1820, Starts first journal, entitled "The Wide World."

1821, Graduates from Harvard and begins teaching at his brother William’s school for young ladies in Boston.

1825, Enters Harvard Divinity School.

1829, Marries Ellen Tucker and is ordained minister at Boston’s Second Church.

1831, Ellen Tucker Emerson dies, at age 19.

1832, Resigns position as minister and sails for Europe.

1833, Meets Wordsworth, Coleridge, J. S. Mill, and Thomas Carlyle. Returns to Boston in November, where he begins a career as a lecturer.

1834, Receives first half of a substantial inheritance from Ellen’s estate (second half comes in 1837).

1835, Marries Lidian Jackson.

1836, Publishes first book, *Nature*.

1838, Delivers the "Divinity School Address." Protests relocation of the Cherokees in letter to President Van Buren.

1841, *Essays* published (contains "Self-Reliance," "The Over-Soul," "Circles," "History").

1842, Son Waldo dies of scarlet fever at the age of 5.

1844, *Essays, Second Series* published (contains "The Poet," "Experience," "Nominalist and Realist").

1847-8, Lectures in England.

1850, Publishes *Representative Men* (essays on Plato, Swedenborg, Montaigne, Goethe, Napoleon).

1851-60, Speaks against Fugitive Slave Law and in support of anti-slavery candidates in Concord, Boston, New York, Philadelphia.

1856, Publishes *English Traits*.

1860, Publishes *The Conduct of Life* (contains "Culture" and "Fate").

1867, Lectures in nine western states.

1870, Publishes *Society and Solitude.* Presents sixteen lectures in Harvard’s Philosophy Department.

1872-3, After a period of failing health, travels to Europe, Egypt.

1875, Journal entries cease.

1882, Dies in Concord.

2. Major Themes in Emerson’s Philosophy

2.1 Education

In "The American Scholar," delivered as the Phi Beta Kappa Address in 1837, Emerson maintains that the scholar is educated by nature, books, and action. Nature is the first in time (since it is always there) and the first in importance of the three. Nature’s variety conceals underlying laws that are at the same time laws of the human mind: "the ancient precept, ‘Know thyself,’ and the modern precept, ‘Study nature,’ become at last one maxim" (87). Books, the second component of the scholar’s education, offer us the influence of the past. Yet much of what passes for education is mere idolization of books -- transferring the "sacredness which applies to the act of creation...to the record." The proper relation to books is not that of the "bookworm" or "bibliomaniac," but that of the "creative" reader who uses books as a stimulus to attain "his own sight of principles." Used well, books "inspire…the active soul" (88). Great books are mere records of such inspiration, and their value derives only, Emerson holds, from their role in inspiring or recording such states of the soul. The "end" Emerson finds in nature is not a vast collection of books, but, as he puts it in "The Poet," "the production of new individuals,… or the passage of the soul into higher forms" (CW3:14)

The third component of the scholar’s education is action. Without it, thought never "ripens into truth." Action is the process whereby what is not fully formed passes into expressive consciousness (91-2). Action is also the scholar’s "dictionary," the source for what she has to say. The true scholar speaks from experience, not in imitation of others; her words, as Emerson puts it, are "are loaded with life…." (Z: 92). The scholar’s education in original experience and self-expression is appropriate, according to Emerson, not only for a small class of people, but for everyone. Its goal is the creation of a democratic nation. Only when we learn to "walk on our own feet" and to "speak our own minds," he holds, will a nation "for the first time exist" (Z: 104-5).

Emerson returned to the topic of education late in his career in "Education," an address he gave in various versions at graduation exercises in the 1860’s. Self-reliance appears in the essay in his discussion of respect. The "secret of Education," he states, "lies in respecting the pupil." It is not for the teacher to choose what the pupil will know and do, but for the pupil to discover "his own secret." The teacher must therefore "wait and see the new product of Nature" (L: 143), guiding and disciplining when appropriate-not with the aim of encouraging repetition or imitation, but with that of finding the new power that is each child’s gift to the world. The aim of education is to "keep" the child’s "nature and arm it with knowledge in the very direction in which it points" (L: 144). This aim is sacrificed in mass education, Emerson warns. Instead of educating "masses," we must educate "reverently, one by one," with the attitude that "the whole world is needed for the tuition of each pupil" (L: 154).

2.2 Process

Emerson is in many ways a process philosopher, for whom the universe is fundamentally in flux and "permanence is but a word of degrees" (CW 2: 179). Even as he talks of "Being," Emerson represents it not as a stable "wall" but as a series of "interminable oceans" (CW3: 42). This metaphysical position has epistemological correlates: that there is no final explanation of any fact, and that each law will be incorporated in "some more general law presently to disclose itself" (CW2: 181). Process is the basis for the succession of moods Emerson describes in "Experience," (CW3: 30), and for the emphasis on the present throughout his philosophy.

Some of Emerson's most striking ideas about morality and truth follow from his process metaphysics: that no virtues are final or eternal, all being "initial," (CW2: 187); that truth is a matter of glimpses, not steady views. We have a choice, Emerson writes in "Intellect," "between truth and repose," but we cannot have both (CW2: 202). Fresh truth, like the thoughts of genius, comes always as a surprise, as what Emerson calls "the newness" (CW3: 40). He therefore looks for a "certain brief experience, which surprise[s] me in the highway or in the market, in some place, at some time..." (Z: 253). This is an experience that cannot be repeated by simply returning to a place or to an object such as a painting. A great disappointment of life, Emerson finds, is that one can only "see" certain pictures once, and that the stories and people who fill a day or an hour with pleasure and insight are not able to repeat the performance.

Emerson's basic view of religion also coheres with his emphasis on process, for he holds that one finds God only in the present: "God is, not was" (Z: 123). In contrast, what Emerson calls "historical Christianity" (114) proceeds "as if God were dead" (Z: 116). Even history, which seems obviously about the past, has its true use, Emerson holds, as the servant of the present: "The student is to read history actively and not passively; to esteem his own life the text, and books the commentary" (CW2:5).

2.3 Morality

Emerson's views about morality are intertwined with his metaphysics of process, and with his perfectionism, his idea that life has the goal of passing into "higher forms" (CW3:14). The goal remains, but the forms of human life, including the virtues, are all "initial" (CW2: 187). The word "initial" suggests the verb "initiate," and one interpretation of Emerson's claim that "all virtues are initial" is that virtues initiate historically developing forms of life, such as those of the Roman nobility or the Confucian *junxi*. Emerson does have a sense of morality as developing historically, but in the context in "Circles" where his statement appears he presses a more radical and skeptical position: that our virtues often must be abandoned rather than developed. "The terror of reform," he writes, "is the discovery that we must cast away our virtues, or what we have always esteemed such, into the same pit that has consumed our grosser vices" (CW2: 187). The qualifying phrase "or what we have always esteemed such" means that Emerson does not embrace an easy relativism, according to which what is taken to be a virtue at any time must actually be a virtue. Yet he does cast a pall of suspicion over all established modes of thinking and acting. The proper standpoint from which to survey the virtues is the ‘new moment‘ "the moment of truth

rather than repose" (CW2:202), in which what once seemed important may appear "trivial" or "vain." From this perspective (or more properly the developing set of such perspectives) the virtues do not disappear, but they may be fundamentally altered and rearranged.

Although Emerson is thus in no position to set forth a system of morality, he nevertheless delineates throughout his work a set of virtues and heroes, and a corresponding set of vices and villains. In "Circles" the vices are "forms of old age," and the hero the "receptive, aspiring" youth (CW2:189). In the "Divinity School Address," the villain is the "spectral" preacher whose sermons offer no hint that he has ever lived. "Self Reliance" condemns virtues that are really "penances" (CW2: 31), and the philanthropy of abolitionists who display an idealized "love" for those far away, but are full of hatred for those close by (CW2: 30).

Conformity is the chief Emersonian vice, the opposite or "aversion" of the virtue of "self-reliance." We conform when we pay unearned respect to clothing and other symbols of status, when we show "the foolish face of praise" or the "forced smile which we put on in company where we do not feel at ease in answer to conversation which does not interest us" (CW2: 32). Emerson criticizes our conformity even to our own past actions-when they no longer fit the needs or aspirations of the present. This is the context in which he states that "a foolish consistency is the hobgoblin of little minds, adored by little statesmen, philosophers and divines" (CW2: 33). There is wise and there is foolish consistency, and it is foolish to be consistent if that interferes with the "main enterprise of the world for splendor, for extent, … the upbuilding of a man" (99).

If Emerson criticizes much of human life, he nevertheless devotes most of his attention to the virtues. Chief among these is what he calls "self-reliance." The phrase connotes originality and spontaneity, and is memorably represented in the image of a group of nonchalant boys, "sure of a dinner…who would disdain as much as a lord to do or say aught to conciliate one...." The boys sit in judgment on the world and the people in it, offering a free, "irresponsible" condemnation of those they see as "silly" or "troublesome," and praise for those they find "interesting" or "eloquent." (CW2: 29). The figure of the boys illustrates Emerson’s characteristic combination of the romantic (in the glorification of children) and the classical (in the idea of a hierarchy in which the boys occupy the place of lords or nobles).

Speaking of "self-reliance," Emerson nevertheless warns-undermining his own previous statements-can be a "poor external way of speaking" (CW 2:40). For it can be taken to mean that there is a self already formed on which we may rely. The "self" on which we are to "rely" is, in contrast, the original self that we are in the process of creating. Such a self, to use a phrase from Nietzsche’s Ecce Homo, "becomes what it is."

For Emerson, the best human relationships require the confident and independent nature of the self-reliant. Emerson’s ideal society is a confrontation of powerful, independent "gods, talking from peak to peak all round Olympus." There will be a proper distance between these gods, who, Emerson advises, "should meet each morning, as from foreign countries, and spending the day together should depart, as into foreign countries" (CW 3:81). Even "lovers," he advises, "should guard their strangeness" (CW3:

82). Emerson portrays himself as preserving such distance in the cool confession with which he closes "Nominalist and Realist," the last of the *Essays, Second Series*:

> I talked yesterday with a pair of philosophers: I endeavored to show my good men that I liked everything by turns and nothing long.... Could they but once understand, that I loved to know that they existed, and heartily wished them Godspeed, yet, out of my poverty of life and thought, had no word or welcome for them when they came to see me, and could well consent to their living in Oregon, for any claim I felt on them, it would be a great satisfaction (CW 3:145).

The self-reliant person will "publish" her results, but she must first learn to detect that spark of originality or genius that is her particular gift to the world. It is not a gift that is available on demand, however, and a major task of life is to meld genius with its expression. "The man," Emerson states "is only half himself, the other half is his expression" (CW 3:4). There are young people of genius, Emerson laments in "Experience," who promise "a new world" but never deliver: they fail to find the focus for their genius "within the actual horizon of human life" (CW 3:31). Although Emerson emphasizes our independence and even distance from one another, then, the payoff for self-reliance is public and social. The scholar finds that the most private and secret of his thoughts turn out to be "the most acceptable, most public, and universally true" (Z: 97). And the great "representative men" Emerson identifies are marked by their influence on the world. Their names-Plato, Moses, Jesus, Luther, Copernicus, even Napoleon-are "ploughed into the history of the world" (Z: 112).

Although self-reliance is central, it is not the only Emersonian virtue. Emerson also praises a kind of trust, and the practice of a "wise skepticism." There are times, he holds, when we must let go and trust to the nature of the universe: "As the traveler who has lost his way, throws his reins on his horse's neck, and trusts to the instinct of the animal to find his road, so must we do with the divine animal who carries us through this world" (3:15). But the world of flux and conflicting evidence also requires a kind of epistemological and practical flexibility that Emerson calls "wise skepticism" (318). His representative skeptic of this sort is Michel de Montaigne, who as portrayed in *Representative Men* is no unbeliever, but a man with a strong sense of self, rooted in the earth and common life, whose quest is for knowledge. He wants "a near view of the best game and the chief players; what is best in the planet; art and nature, places and events; but mainly men" (CW4: 91). Yet he knows that life is perilous and uncertain, "a storm of many elements," the navigation through which requires a flexible ship, "fit to the form of man." (CW4: 91).

2.4 Christianity

The son of a Unitarian minister, Emerson attended Harvard Divinity School and was employed as a minister for almost three years. Yet he offers a deeply felt and deeply reaching critique of Christianity in the "Divinity School Address," flowing from a line of argument he establishes in "The American Scholar." If the one thing in the world of value is the active soul, then religious institutions, no less than educational institutions, must be judged by that standard. Emerson finds that contemporary Christianity

deadens rather than activates the spirit. It is an "Eastern monarchy of a Christianity" in which Jesus, originally the "friend of man," is made the enemy and oppressor of man. A Christianity true to the life and teachings of Jesus should inspire "the religious sentiment"-a joyous seeing that is more likely to be found in "the pastures," or "a boat in the pond" than in a church. Although Emerson thinks it is a calamity for a nation to lose the capacity to worship (Z: 122) he finds it strange that, given the "famine of our churches" (Z: 117) anyone should attend them. He therefore calls on the Divinity School graduates to breathe new life into the old forms of their religion, to be friends and exemplars to their parishioners, and to remember "that all men have sublime thoughts; that all men value the few real hours of life; they love to be heard; they love to be caught up into the vision of principles" (Z: 124).

2.5 Power

Power is a theme in Emerson’s early writing, but it becomes especially prominent in such middle- and late-career essays as "Experience," "Montaigne; or the Skeptic" "Napoleon," and "Power." Power is related to action in "The American Scholar," where Emerson holds that a "true scholar grudges every opportunity of action passed by, as a loss of power" (Z: 92). It is also a subject of "Self-Reliance," where Emerson writes of each person that "the power which resides in him is new in nature" (CW2:28). In "Experience" Emerson speaks of a life which "is not intellectual or critical, but sturdy" (CW3:294); and in "Power" he celebrates the "bruisers" (P: 372) of the world who express themselves rudely and get their way. The power in which Emerson is interested, however, is more artistic and intellectual than political or military. In a characteristic passage from "Power," he states:

> In history the great moment is, when the savage is just ceasing to be a savage, with all his hairy Pelasgic strength directed on his opening sense of beauty:-and you have Pericles and Phidias,-not yet passed over into the Corinthian civility. Everything good in nature and the world is in that moment of transition, when the swarthy juices still flow plentifully from nature, but their astringency or acridity is got out by ethics and humanity" (P: 375).

Power is all around us, but it cannot always be controlled. It is like "a bird which alights nowhere," hopping "perpetually from bough to bough" (CW3:34). Moreover, we often cannot tell at the time when we exercise our power that we are doing so: happily we sometimes find that much is accomplished in "times when we thought ourselves indolent" (CW3:28).

2.6 Unity and Moods

At some point in many of his essays and addresses, Emerson enunciates, or at least refers to, a great vision of unity. He speaks in "The American Scholar" of an "original unit" or "fountain of power" (Z: 84), of which each of us is a part. He writes in "The Divinity School Address" that each of us is "an inlet into the deeps of Reason." And in "Self-Reliance," the essay that more than any other celebrates individuality, he writes of "the resolution of all into the ever-blessed ONE" (CW 2:40). "The Oversoul" is Emerson’s most sustained discussion of "the ONE," but he does not, even there, shy away from the seeming conflict between the reality of process and the reality of an ultimate metaphysical unity. How

can the vision of succession and the vision of unity be reconciled?

Emerson never comes to a clear or final answer. One solution he both suggests and rejects is an unambiguous idealism, according to which a nontemporal "One" or "Oversoul" is the only reality, and all else is illusion. He suggests this, for example, in the many places where he speaks of waking up out of our dreams or nightmares. But he then portrays that to which we awake not simply as an unchanging "ONE," but as a process or succession: a "growth" or "movement of the soul" (CW2: 189); or a "new yet unapproachable America" (CW3: 259).

Emerson undercuts his visions of unity (as of everything else) through what Stanley Cavell calls his "epistemology of moods." According to this epistemology, most fully developed in "Experience" but present in all of Emerson's writing, we never apprehend anything "straight" or in-itself, but only under an aspect or mood. Emerson writes that life is "a train of moods like a string of beads," through which we see only what lies in each bead's focus (CW3: 30). The beads include our temperaments, our changing moods, and the "Lords of Life" which govern all human experience. The Lords include "Succession," "Surface, "Dream," "Reality," and "Surprise." Are the great visions of unity, then, simply aspects under which we view the world?

Emerson's most direct attempt to reconcile succession and unity, or the one and the many, occurs in the last essay in the *Essays, Second Series*, entitled "Nominalist and Realist." There he speaks of the universe as an "old Two-face…of which any proposition may be affirmed or denied" (CW3: 144). As in "Experience," Emerson leaves us with the whirling succession of moods. "I am always insincere," he skeptically concludes, "as always knowing there are other moods" (CW3: 145). But Emerson enacts as well as describes the succession of moods, and he ends "Nominalist and Realist" with the "feeling that all is yet unsaid," and with at least the idea of some universal truth (CW3: 363).

3. Some Questions about Emerson

3.1 Consistency

Emerson routinely invites charges of inconsistency. He says the world is fundamentally a process and fundamentally a unity; that it resists the imposition of our will and that it flows with the power of our imagination; that travel is good for us, since it adds to our experience, and that it does us no good, since we wake up in the new place only to find the same " sad self" we thought we had left behind (CW2: 46).

Emerson's "epistemology of moods" is an attempt to construct a framework for encompassing what might otherwise seem contradictory outlooks, viewpoints, or doctrines. Emerson really means to "accept," as he puts it, "the clangor and jangle of contrary tendencies" (CW3: 36). He means to be irresponsible to all that holds him back from his self-development. That is why, at the end of "Circles," he writes that he is "only an experimenter…with no Past at my back" (CW2: 188). In the world of flux that he depicts in that essay, there is nothing stable to be responsible to: "every moment is new; the past

is always swallowed and forgotten, the coming only is sacred" (CW2: 189).

Despite this claim, there is considerable consistency in Emerson's essays and among his ideas. To take just one example, the idea of the "active soul"-mentioned as the "one thing in the world, of value" in "The American Scholar-is a presupposition of Emerson's attack on "the famine of the churches" (for not feeding or activating the souls of those who attend them); it is an element in his understanding of a poem as "a thought so passionate and alive, that, like the spirit of a plant or an animal, it has an architecture of its own …." (CW3: 6); and, of course, it is at the center of Emerson's idea of self-reliance. There are in fact multiple paths of coherence through Emerson's philosophy, guided by ideas discussed previously: process, education, self-reliance, and the present.

3.2 Early and Late Emerson

It is hard for an attentive reader not to feel that there are important differences between early and late Emerson: for example, between the buoyant *Nature* (1836) and the weary ending of "Experience" (1844); between the expansive author of "Self-Reliance" (1841) and the burdened writer of "Fate" (1860). Emerson himself seems to advert to such differences when he writes in "Fate": "Once we thought positive power was all. Now we learn that negative power, or circumstance, is half" (Z: 369). Is "Fate" the record of a lesson Emerson had not absorbed in his early writing, concerning the multiple ways in which circumstances over which we have no control -- plagues, hurricanes, temperament, sexuality, old age-constrain self-reliance or self-development?

"Experience" is a key transitional essay. "Where do we find ourselves?" is the question with which it begins. The answer is not a happy one, for Emerson finds that we occupy a place of dislocation and obscurity, where "sleep lingers all our lifetime about our eyes, as night hovers all day in the boughs of the fir-tree" (CW3: 27). An event hovering over the essay, but not disclosed until its third paragraph, is the death of his five-year old son Waldo. Emerson finds in this episode and his reaction to it an example of an "unhandsome" general character of existence-it is forever slipping away from us, like his little boy.

"Experience" presents many moods. It has its moments of illumination, and its considered judgment that there is an "Ideal journeying always with us, the heaven without rent or seam" (CW3: 41). It offers wise counsel about "skating over the surfaces of life" and confining our existence to the "mid-world." But even its upbeat ending takes place in a setting of substantial "defeat." "Up again, old heart!" a somewhat battered voice states in the last sentence of the essay. Yet the essay ends with an assertion that in its great hope and underlying confidence chimes with some of the more expansive passages in Emerson's writing. The "true romance which the world exists to realize," he states, "will be the transformation of genius into practical power" (CW3: 49).

Despite important differences in tone and emphasis, Emerson's assessment of our condition remains much the same throughout his writing. There are no more dire indictments of ordinary human life than in the early work, "The American Scholar," where Emerson states that "Men in history, men in the world of today, are bugs, are spawn, and are called 'the mass' and 'the herd.' In a century, in a millennium, one or

two men; that is to say, one or two approximations to the right state of every man" (99). Conversely, there is no more idealistic statement in his early work than the statement in "Fate" that "[t]hought dissolves the material universe by carrying the mind up into a sphere where all is plastic" (377). All in all, the earlier work expresses a sunnier hope for human possibilities, the sense that Emerson and his contemporaries were poised for a great step forward and upward; and the later work, still hopeful and assured, operates under a weight or burden, a stronger sense of the dumb resistance of the world.

3.3 Sources and Influence

Emerson read widely, and gave credit in his essays to the scores of writers from whom he learned. He kept lists of literary, philosophical, and religious thinkers in his journals and worked at categorizing them.

Among the most important writers for the shape of Emerson’s philosophy are Plato and the Neoplatonist line extending through Plotinus, Proclus, Iamblichus, and the Cambridge Platonists. Equally important are writers in the Kantian and Romantic traditions (which Emerson probably learned most about from Coleridge’s *Biographia Literaria*). Emerson read avidly in Indian, especially Hindu, philosophy, and in Confucianism. There are also multiple empiricist, or experience-based influences, flowing from Berkeley, Wordsworth and other English Romantics, Newton’s physics, and the new sciences of geology and comparative anatomy. Other writers whom Emerson often mentions are Anaxagoras, St. Augustine, Francis Bacon, Jacob Behmen, Cicero, Goethe, Heraclitus, Lucretius, Mencius, Pythagoras, Schiller, Thoreau, August and Friedrich Schlegel, Shakespeare, Socrates, Madame de Staël and Emanuel Swedenborg.

Emerson’s works were well known throughout the United States and Europe in his day. Nietzsche read German translations of Emerson’s essays, copied passages from "History" and "Self-Reliance" in his journals, and wrote of the *Essays*: that he had never "felt so much at home in a book." Emerson’s ideas about "strong, overflowing" heroes, friendship as a battle, education, and relinquishing control in order to gain it, can be traced in Nietzsche’s writings. Other Emersonian ideas-about transition, the ideal in the commonplace, and the power of human will permeate the writings of such classical American pragmatists as William James and John Dewey; and his philosophy is a primary source for Stanley Cavell’s contemporary writing on "moral perfectionism."
